

REMARKS

Entry of the above-noted amendments prior to the examination of this application is respectfully requested. The amendments to the specification and abstract are for correcting typographical and/or grammatical errors found therein, and to place the specification and abstract in better form for U.S. practice. No new matter has been added by these amendments.

The amendments to the claims are solely for the purpose of clarifying the subject matter of applicants' invention, and are not for any purpose related to patentability. Applicants submit that none of the amendments to the claims are intended to narrow the scope of same, nor do they enter any new matter into the application.

If, for any reason, the Examiner believes that the entry of these amendments cannot be made at this time, it is respectfully requested that he telephone applicants' undersigned counsel at (908)654-5000 in order to overcome any such objection the Examiner may have.

No fee is believed necessary for this amendment. However, if there are any fees to be incurred in connection herewith, the Examiner is authorized to charge Deposit Account No. 12-1095 therefor.

Dated: February 11, 2003

MARKED UP COPY OF ABSTRACT

ABSTRACT

Technology Center 2100

A data processing system, apparatus and a data processing method are provided to verify and validate data. Cryptographic processes employ keys to encrypt the data, check the data and prevent tampering with the data. The data may include header information such as compressed contents or an expansion processing program used to process the data. efficiently ascertain that data are valid, prevent encryption processing key data from leaking, eliminate illegal use of contents data, restrict contents utilization, apply a different plurality of data formats to contents and efficiently execute reproduction processing of compressed data. The verification process of partial data is executed by collating the integrity partial data as check values for a combination of partial data of a content, and the verification process of the entirety of the combination of partial data is executed by collating partial integrity check value verifying integrity check values that verify the combination of the partial integrity check values. Master keys to generate individual keys necessary for a process of such as data encryption are stored in the storage section and keys are generated as required. An illegal device list is stored in the header information of a content and referred to when data is used. Keys specific to a data processing apparatus and common keys are stored and the keys are selectively used according to the content use restriction. Plural content blocks are coupled, and at least a part of the content blocks is applied to an encryption process by an encryption key K_{con} , then encryption key data that is the encryption key K_{con} encrypted by an encryption key K_{dis} is stored in the header section. A content data is made of compression data and an

~~expansion processing program or a combination of types of
compression programs and the reproducing apparatus can
determine an expansion program applicable to a compressed
content.~~

DESCRIPTION

DATA PROCESSINGS APPARATUS AND DATA PROCESSING METHOD

Technical Field BACKGROUND OF THE INVENTION

[0001] The present invention relates to a data processing apparatus, and a data processing method, and more particularly, to a method and apparatus for verifying that data constituting a data content ~~are~~is valid, that is, checking whether or not the data ~~have~~has been tampered with_T; as well as a method for imparting verification values_T; and also to an apparatus and a method capable of enhancing security by generating individual keys necessary for encryption processing using master keys corresponding to their respective individual keys. Moreover the present invention provides a configuration that eliminates illegal usage of contents data. ~~or~~ ~~More~~ More specifically, the invention relates to an apparatus and a method capable of identifying illegal reproduction devices and eliminateing illegal use of contents. Furthermore, the present invention relates to an apparatus and a method capable of easily setting contents only available to the data processing apparatus using contents data and contents data also available to other data processing apparatuses based on information specific to the data processing apparatus, etc. Still further, the present invention relates to a method, apparatus and verification value assignment method for verifying the validity of data configuring data contents, that is, verifying the presence or absence of tampering.

[0002] Furthermore, the present invention relates to a data processing apparatus, a content data generating method, and a data processing method that realizes a content data configuration ~~enabling~~ to provide and utilize content data under a ~~high~~ security management. The content data is in a configuration in which data (including at least any one of voice information, image information and program data) is applied to encryption processing. ~~‡~~The content data is provided to a content user together with various kinds of header information, and the content user performs reproduction, execution, or storing processing in a recording device.

[0003] Still further, the present invention relates to a data processing apparatus, a data processing method and a content data generating method for providing a configuration for efficiently executing reproduction processing. For instance, the in the case in which data contents are may be compressed voice data, image data or the like. and More specifically, for enabling to have it enables a configuration of ~~the~~ content data in which compressed data and an expansion processing program are combined to retrieve and extract an applicable expansion processing program based on header information of compressed data contents in which an applied expansion processing program is stored as header information to execute reproduction processing.

[0004] ~~Further yet, t~~The present invention further relates to a configuration and method for reproducing various contents such as sounds, images, games, or programs which are available through various recording media. such as The recording media include DVDs, or CDs, or wire or radio communication means such as CATV, the Internet, or and satellite communication. Reproduction occurs in a recording and reproducing device owned by of a user. and storing tThe contents are stored in an exclusive recording device such as, for example, a memory card, a hard disk, or a CD-R, CD-ROM. realizing a configuration for imposing use limitations desired by a content distributor when a content stored in the recording device is used, and providing security such that the distributed content will not be illegally used by a third person other than regular users. Use limitations, such as limitations selected by a content distributor, are stored along with content to provide security such that the distributed content will not be illegally used.

~~Background Art~~

~~DESCRIPTION OF THE RELATED ART~~

[0005] Various data such as game programs, sound data, image data, or documenting programs (these are hereafter referred to as "contents") are now distributed via a network such as the Internet or via distributable storage media such as DVDs or CDs. These distributed contents can be stored in a

recording device such as a memory card or a hard disk ~~which that~~ is attached to a recording and reproducing apparatus such as a ~~P~~personal ~~E~~computer (PC) or a game apparatus ~~that~~ ~~of is owned by~~ a user so that once stored, the contents can be reproduced from the storage media.

[0006] The Mmain components of a memory card used in a conventional information apparatus such as a video game apparatus or a PC include a ~~connection~~control means for controlling operations, a connector for connection to a slot connected to the ~~connection~~control means and formed in the information apparatus, ~~and~~ non-volatile memory connected to the control means for storing data, ~~and others~~. The non-volatile memory provided in the memory card comprises, for example, an EEPROM, a flash memory, or the like.

[0007] Various contents such as data or programs that are stored in the memory card are invoked from the non-volatile memory in response to a user's command from an information apparatus main body such as a game apparatus or a PC. ~~which is~~ The game apparatus or PC can be used as a reproduction apparatus or to respond to a user's command provided via a connected input means. ~~and~~ The contents are reproduced from the information apparatus main body or from a display, speakers, or the like which are connected thereto.

[0008] ~~Many s~~Software contents such as game programs, music data, or image data generally have their distribution rights held by their creators or sellers. Thus, in distributing ~~these~~this contents, a configuration is generally used which places specified limitations on the usage. ~~That is~~ means the use of software is permitted only for regular users so as to prevent unauthorized copying or the like. In other words, ~~that is~~ security is taken into consideration.

[0009] One method for realizing limitations on the use by a user is a process for encrypting ~~a~~distributed content. This process comprises ~~a means for~~ distributing various contents such as sound data, image data, or game programs which are encrypted, for example, via the Internet, and decrypting ~~at the~~ distributed content that has been encrypted. ~~content~~ Decryption takes place only for people confirmed to be regular

users. ~~Distributing the various content—the means~~
corresponding to a configuration with a means for imparting a
decryption key.

[0010] Encrypted data can be ~~returned to available~~
decrypted ~~data into, for example, {plain text}—obtained~~ by a
decryption process based on a predetermined procedure. ~~Such a~~
data encrypting and decrypting method that uses an encryption
key for an information encrypting process while using a
decryption key for such a decryption process is conventionally
known.

[0011] There are various types of aspects of data
encrypting and decrypting methods using an encryption key and
a decryption key. ~~an~~ One example is ~~what is~~ called a common
key cryptosystem. The common key cryptosystem uses a common
encryption key ~~used for~~ a data encrypting process and a common
decryption key ~~used for~~ a data decrypting process and imparts
these common keys ~~used for~~ the encryption and decryption
processes, to regular users while excluding data accesses by
illegal users that have no key. A representative example of
this cryptosystem is the ~~DES (Data Encryption Standard)~~ (DES).

[0012] The encryption and decryption keys used for the
encryption and decryption processes are obtained, for example,
by applying a one-way function such as a hash function based
on a password or the like. The one-way function makes it
difficult to determine ~~its~~ the input of the function from
~~its~~ the output of the function. For example, a password decided
by a user is used as an input to ~~apply~~ a one-way function so
as to generate an encryption key and a decryption ~~keys~~ based
on ~~an~~ the output from the one-way function. Determining the
password (which is the original data for the keys) from the
~~thus obtained a encryption and decryption keys, the password,~~
~~which is the original data for the keys,~~ is substantially
impossible.

[0013] In addition, a method called a "public key
cryptosystem" uses different algorithms for a process based on
an encryption key used for encryption and for a process based
on a decryption key used for decryption. The public key
cryptosystem uses a public key available to unspecified users

so that an encrypted document for a particular individual is decrypted using a public key issued by this particular user. The document encrypted with the public key can only be decrypted with a secret key corresponding to the public key used for the decryption process. Since the secret key is owned by the individual that has issued the public key, the document encrypted with the public key can be decrypted only by individuals having the secret key. A representative public key cryptosystem is the RSA (Rivest-Shamir-Adleman) encryption.

[0014] The use of such a cryptosystem enables encrypted contents to be decrypted only for regular users. A conventional content distributing configuration employing such a cryptosystem will be described ~~in brief~~ with reference to Fig. 1.

[0015] Fig. 1 shows an example of a configuration in which a reproduction means 10 such as a PC ~~(Personal Computer)~~ or a game apparatus reproduces a program, sound or video data, or the like (content) obtained from a data providing means such as a DVD, ~~a~~ or CD 30, or the Internet 40 and wherein data obtained from the DVD, ~~or~~ CD 30, Internet 40, or the like are stored in a storage means 20 such as a floppy disk, a memory card, a hard disk, or the like.

[0016] The content, such as a program, ~~or~~ sound or video data, ~~are~~ is provided to a user having the reproduction means 10. A regular user obtains an encryption data as well as key data that are their encryption and decryption keys.

[0017] The reproduction means 10 has a CPU 12 to reproduce input data by means of a reproduction process section 14. The reproduction process section 14 decrypts encrypted data to reproduce content such as a provided program, ~~and the content such as~~ sound or image data.

[0018] The regular user saves the content ~~such as the program and data~~ to the a storage means 20 in order to use the provided program again. The reproduction means 10 has a saving storage process section 13 for executing this content saving storage process. The storage saving process section 13 encrypts and saves the data in order to prevent the data stored in the storage means 20 from being illegally used.

[0019] A content encrypting key is used to encrypt the content. The ~~saving~~storage process section 13 uses the content encrypting key to encrypt the content and then stores the encrypted content in a storage section 21 of the storage means 20 such as a ~~FD (Floppy Disk)~~ (FD), a memory card, or a hard disk.

[0020] To obtain and reproduce the stored content from the storage means 20, the user obtains encrypted data from the storage means 20 and causes the reproduction process section 14 of the reproduction means 10 to execute the decryption process using a content decrypting key. ~~That is,~~ the decryption key is used in order to obtain and reproduce decrypted data from the encrypted data.

[0021] According to the conventional example of the configuration shown in Fig. 1, the stored content is encrypted in the storage means 20 (such as a floppy disk or memory card) and thus cannot be read externally. When, however, this floppy disk is to be reproduced by ~~means of~~ a reproduction means of another information apparatus, such as PC or game apparatus, the reproduction is impossible unless the reproduction means has the same content key, ~~that is,~~ (i.e., the same decryption key for decrypting the encrypted content). Accordingly, to implement a form available to a plurality of information apparatuses, a common decryption key must be provided to users.

[0022] The use of a common content encrypting key, however, means that there will be a higher possibility of ~~disorderly~~ distributing the encryption process key to users not having a regular license. Consequently, it may not be possible to prevent the illegal use of the content by users not having the regular license ~~cannot be prevented.~~ and Thus, it will be difficult to exclude the illegal use in PCs, game apparatuses, or the like by users who ~~which~~ do not have the regular license.

[0023] In case that key information ~~leaks~~ leaks from one of the apparatuses, the use of common content encrypting key and decryption key can cause damage to the whole system which utilizes the keys.

[0024] Furthermore, in an environment using a common key as described above, it is possible to easily copy, for example, a

content created on a certain PC and initially saved to a storage means such as a memory card or floppy disk, to ~~another~~ a second floppy disk. Consequently, ~~a use form~~ using the second copied floppy disk instead of the original content data will be possible, so that a large number of copied content data available to information apparatuses such as game apparatuses or PCs may be created or tampered.

[0025] A method which is conventionally used ~~which contains~~ includes ~~a~~ verifying an integrity check value in content data ~~for~~ to checking the validity of the data. That is, in order to determine whether or not the data have been tampered ~~and which then causes~~ with, a recording and reproducing device ~~to~~ collates an integrity check value (generated based on the data to be verified) with the integrity check value contained in the content data to verify the data.

[0026] The integrity check value for the data contents, however, is generally generated for the entire set of data. ~~and~~ Collating the integrity check value generated for the entire set of data requires a integrity check value to be generated for the entire set of data to be checked. If, for example, a integrity check value (ICV) is to be determined using a Message Authentication Code (MAC) generated in a DES-CBC (Cipher Block Chaining) mode, the DES CBC process must be executed on the entire set of data. The amount of such calculations increases linearly with the data length, thereby disadvantageously reducing processing efficiency.

~~Description of the Invention~~ SUMMARY OF THE INVENTION

[0027] The present invention solves the above problems ~~in~~ with the conventional art. ~~and is to~~ The present invention provides, as a first object of the invention, a data processing apparatus and method and a data verifying value imparting method, which efficiently confirms the validity of data and efficiently executes a download process for a recording device. The download process is executed after the verification. a reproduction process is also executed after the verification, along with ~~and other processes, as well as.~~

Aa program providing medium for use in this apparatus and these methods is also presented.

[0028] Furthermore, as techniques for limiting the use of contents data to authorized users, various kinds of encryption processing are available, such as data encryption, data decryption, data verification, and signature processing. However, executing these kinds of encryption processing requires common secret information. For example, common secret information is used in key information applied to encryption and decryption of contents data, or to an authentication key used for authentication ~~to be shared~~ between two apparatuses, ~~that is,~~ (i.e., apparatuses between which contents data is transferred or apparatuses between which authentication processing is executed).

[0029] Therefore, in the case where key data, (which is shared secret information), is leaked from either of the two apparatuses, the contents encryption data (using the shared key information) can also be decrypted by a third party who has no license, thus allowing illegal use of contents. The same is true for the case where an authentication key is leaked, ~~which will~~ This can lead to establishing an authentication for an apparatus with no license. Leakage of keys, therefore, has consequences that ~~threatening~~ the entire system.

[0030] The present invention is intended to solve these problems.

[0031] The second object of the invention is to provide a data processing apparatus, data processing system and data processing method with enhanced security in encryption processing. The data processing apparatus of the present invention does not store individual keys necessary to execute encryption processing such as data encryption, data decryption, data verification, authentication processing and signature processing in a storage section. Instead, the data processing apparatus stores master keys to generate these individual keys. The master keys are stored in the storage section ~~instead~~ and allows an encryption processing section to generate necessary

individual keys based on the master keys and identification data of the apparatus or data.

[0032] Furthermore, it is possible to maintain a certain degree of security by supplying data encrypted contents~~data encrypted~~. However, in the case where various encryption keys stored in memory are read and leaked through illegal reading of memory, key data, etc. ~~is leaked~~ and copied on a recorder/reproducer without any authorized license, contents may be illegally used using the copied key information.

[0033] It is ~~thea~~ third object of the present invention to provide a data processing apparatus, data processing method and ~~contents~~ data generation method in a configuration capable of excluding such illegal reproducers~~r~~. That is, a configuration that is capable of identifying illegal reproducers and not allowing the identified illegal reproducers to execute processing such as reproduction and downloading of ~~contents~~ data.

[0034] Furthermore, techniques for limiting the use of ~~contents~~ data to authorized users include encryption processing using predetermined encryption keys, for example, signature processing. However, conventional encryption ~~processing~~ using signature processing generally has a signature key common to all entities using the contents in a system.~~and s~~ Such a common signature key allows different apparatuses to use common contents~~r~~, ~~which involves a problem of~~ This can leading to illegal copies of contents.

[0035] It is possible to store encrypted contents~~encrypted~~ using a unique password, etc., but the password may be stolen. It is also possible to decrypt athe same encrypted data ~~contents~~ data by entering athe same password through different reproducers~~r~~. However, ~~but~~ it is difficult for a conventional security configuration to implement a system that can identify a reproducer ~~to that only~~ allows only the reproducer to use the contents.

[0036] The present invention has been implemented to solve the above problems of the prior arts~~and~~. It is thea fourth object of the present invention to provide a data processing apparatus and data processing method capable of allowing only

a specific data processing apparatus to reproduce contents according to contents utilization restrictions. This is done by making it possible to selectively use both an apparatus-specific key, which is specific to a data processing apparatus, and a system common key, which is common to other data processing apparatuses.

[0037] Furthermore, ~~here is~~ encryption processing of content data is used as a method of limiting utilization of content data to only authorized users. However, there are various kinds of content data, such as voice information, image information and program data, ~~and.~~ ~~There are various kinds of contents in cases such as a case in which~~ (a) where all content data is required to be encrypted, and (b) ~~a case in which~~ where a part requiring encryption processing and a part not requiring encryption processing are mixed.

[0038] Applying encryption processing uniformly to ~~such~~ various contents may generate unnecessary decryption processing in reproduction processing of the contents, ~~or.~~ It may also generate unfavorable situations in terms of processing efficiency and processing speed. For example, for data such as music data ~~te~~in which real time reproduction is essential, it is desirable to have a content data structure that can ~~be applied~~ apply decryption processing in high speed processing ~~speed.~~

[0039] The present invention solves such problems. It is ~~the~~ a fifth object of the present invention to provide a data processing apparatus, a content data generating method and a data processing method ~~that enables~~ to ~~apply to a content~~ various data structures corresponding to types of content data to specific content. In other words, ~~i.e.,~~ various different data formats are provided corresponding to the content, ~~and~~ This enables generation and processing of content data in a manner that has high security and easy to ~~be~~ utilized in reproduction, execution and the like.

[0040] Furthermore, voice data, image data and the like that are decrypted are then ~~outputted~~ to an AV output section to be reproduced. Nowadays, often times, ~~many of~~ contents ~~are~~ is compressed and stored in a storage medium or distributed.

It is therefore necessary to expand the compressed data before reproducing it. For example, if voice data is ~~MP-3-compressed~~ in the MP-3 format, the voice data ~~is~~will be decrypted by a MP3 decoder ~~to be output~~. And ~~i~~f content data is image data which is ~~MP-3-compressed~~ in the MP-3 format, the voice data is expanded by a MPEG2 decoder to be output.

[0041] However, as there are various kinds of compression processing and expansion processing programs, even if compressed data is provided from a content provider via a medium or a network, it ~~is~~can be impossible to reproduce the data with a reproducing apparatus that does not have a compatible expansion program.

[0042] It is ~~the~~a sixth object of the present invention to provide a configuration for efficiently executing reproduction processing of compressed data~~7~~. ~~t~~That is, a data processing apparatus, a data processing method and a content data generating method for efficiently executing reproduction processing are presented in the case in which the contents ~~are~~is compressed voice data, image data or the like.

[0043] The foregoing objects and other objects of the invention have been achieved by ~~the provision of~~ providing a data processing apparatus and a data processing method.

[0044] A first aspect of the present invention is~~+~~ a data processing apparatus for processing content data. The content data is provided by a recording or communication medium~~7~~. ~~characterized in that said~~ The data processing apparatus comprises~~+~~ a cryptography process section for executing a cryptography process on the content data~~7~~ and a control section for executing control for the cryptography process section~~7~~, ~~and~~ ~~t~~The cryptography process section ~~is configured to generate~~s partial integrity check values as integrity check values for a partial data set containing ~~one or more~~ partial data obtained by a content data-constituting section. The content data-constituting section assembles partial data into a plurality of parts. The cryptography process section, collates ~~the generated~~ integrity check values to verify the partial data, generates an intermediate integrity check value based on a partial integrity check value set ~~data string~~

containing at least one ~~or more~~ of the partial integrity check values, and uses the ~~generated~~ intermediate integrity check value to verify the ~~entirety of the plurality of~~ partial data sets ~~corresponding to the plurality of partial integrity check values constituting the partial integrity check value set.~~

[0045] Further, one embodiment of the data processing apparatus according to the present invention is characterized in that the partial integrity check values ~~is~~ are generated by means of a cryptography process with a partial-check-value-generating key applied thereto~~7~~. The cryptography process uses ~~using~~ partial data ~~to be checked7~~, as a message~~7~~. ~~7~~ The intermediate integrity check value is generated by means of ~~at~~ the cryptography process with an general-check-value-generating key applied thereto, using a ~~the~~ partial integrity check value set ~~data string to be checked7~~, as a ~~the~~ message~~7~~, and ~~7~~ The cryptography process section is configured to store the partial ~~integrity check value-generating~~ key ~~value~~ and the general ~~integrity check value-generating~~ key.

[0046] Further, ~~one~~ another embodiment of the data processing apparatus according to the present invention is characterized in that the cryptography process has plural types of partial-check-value-generating keys corresponding to ~~said~~ generated partial integrity check values.

[0047] Further, ~~one~~ Another embodiment of the data processing apparatus according to the present invention is characterized in that the cryptography process is a DES cryptography process~~7~~, and ~~7~~ The cryptography process section is configured to execute the DES cryptography process.

[0048] Further, ~~one~~ yet another embodiment of the data processing apparatus according to the present invention is characterized in that the partial integrity check values ~~is~~ are ~~a~~ message authentication codes (MAC). The MAC is generated in a DES-CBC mode using ~~said~~ partial data to be checked~~7~~, as a ~~the~~ message~~7~~. ~~7~~ The intermediate integrity check value is one of the ~~a~~ message authentication codes (MAC) generated in a ~~the~~ DES-CBC mode using a ~~the~~ partial integrity check value set ~~data string to be checked7~~, as a ~~the~~ message~~7~~, and ~~7~~ The

cryptography process section is configured to execute the cryptography process in the DES-CBS mode.

[0049] Further, ~~in another~~^{one} embodiment of the data processing apparatus according to the present invention, ~~is characterized in that Triple DES is applied in part of a message string to be processed in the DES-CBC mode-based cryptography process configuration of the cryptography process section, Triple DES is applied only in part of a message string to be processed.~~

[0050] Further, ~~one~~ⁱⁿ another embodiment of the data processing apparatus according to the present invention, ~~is characterized in that the data processing apparatus has a signature key.~~, ~~and t~~^e The cryptography process section is configured to apply a value generated from the intermediate integrity check value by means of the signature key ~~applied cryptography process as a collation value for data verification.~~

[0051] Further, ~~one~~^{yet} another embodiment of the data processing apparatus according to the present invention is characterized in that the ~~data processing apparatus~~^{signature key} has a plurality of different signature keys, ~~as signature keys, and t~~^e The cryptography process section is configured to apply one of the plurality of different signature keys, which is selected depending on a localization of the content data, to the cryptography process for the intermediate integrity check value in order to obtain the collation value for data verification.

[0052] Further, ~~in another~~^{one} embodiment, ~~of the data processing apparatus according to the present invention is characterized in that the data processing apparatus has a common signature key common to all entities of a system for executing a data verifying process, and The data processing apparatus also has an apparatus-specific signature key specific to each apparatus that executes a the data verifying process.~~

[0053] Further, ~~one~~^{yet} another embodiment of the data processing apparatus according to the present invention is characterized in that the partial integrity check values

contains at least one or more header section integrity check values. The header section integrity check value is generated for intra-header-section data partly constituting data. ~~and~~ The partial integrity check values also contain at least one or more content integrity check values generated for content block data partly constituting the data. ~~and t~~ The cryptography process is configured to generate at least one or more header section integrity check values for thea partial data set in the intra-header-section data to execute a the collation process. The cryptography process also generates at least one or more content integrity check values for saida partial data set in the intra-content-section data to execute asaid collation process. ~~and f~~ Further, the cryptography process generates a general integrity check value based on all of the header section integrity check values and the content integrity check values generated, to execute athe collation process in order to verify the data.

[0054] Further, one embodiment of the data processing apparatus according to the present invention is characterized in that the partial integrity check values contains at least one or more header section integrity check values generated for intra-header-section data partly constituting data. ~~and t~~ The cryptography process is configured to generate at least one or more header section integrity check values for thea partial data set in the intra-header-section data to execute a collation process. ~~and~~ The cryptography process further generates a general integrity check value based on the at least on the one or more header section integrity check values generated and on content block data. The content block data constitutesing part of the data, ~~to execute a~~ The collation process is executed in order to verify the data.

[0055] Further, ~~onean~~ onean embodiment of the data processing apparatus according to the present invention ~~is characterized by further comprisesing~~ comprises a recording device for storing data validated by the cryptography process section.

[0056] ~~Further,~~ Another embodiment of the data processing apparatus according to the present invention is characterized in that ~~the control section is configured so~~

~~that if in the process executed by the cryptography process section to collate the partial integrity check value, the collation is not established, and the control section suspends the process for storing of the data in the recording device if a process of collating the partial integrity check values is not established in the cryptography process executed by the cryptography process section.~~

[0057] Further, ~~yet another~~embodiment of the data processing apparatus according to the present invention ~~is characterized by further comprising~~includes a reproduction process section for reproducing data validated by the cryptography process section.

[0058] Further, one embodiment of the data processing apparatus according to the present invention is characterized in that ~~if in the process executed by the cryptography process section to collate the partial integrity check value, the collation is not established, and the control section suspends reproducing of the data~~the reproduction process in the reproduction process section if a process of collating the partial integrity check values is not established in the cryptography process executed by the cryptography process section.

[0059] Further, ~~Another~~embodiment of the data processing apparatus according to the present invention ~~is characterized by comprising~~further includes a control means. The control means for collatesing only the header section integrity check values in the data during the cryptography process executed by the cryptography process section to collate the partial integrity check values. The control means thenand transmittstransmitsing to the reproduction process section the data for which collation of the header section integrity check values has been established,~~to the reproduction process section for reproduction.~~

[0060] Moreover, a second aspect of the present invention is a data processing apparatus for processing content data provided by a recording or communication medium, ~~characterized in that said~~ The data processing apparatus comprises a cryptography process section for executing a

cryptography process on the content data, and a control section for executing control for the cryptography process section. ~~and~~ If the data to be verified is encrypted data, ~~then the cryptography process section: is configured to generates, if data to be verified are encrypted,~~ integrity check values for the data ~~to be verified~~ by means of a signature data-applied cryptography process. The cryptography process section generates the integrity check values from data on arithmetic operation results obtained by executing an arithmetic operation process on decrypted data obtained by executing a decryption process on the encrypted data.

[0061] Further, one embodiment of the data processing apparatus according to the present invention is characterized in that the arithmetic operation process comprises performing an exclusive-OR operation on the decrypted data at every ~~predetermined bytes. and~~ The decrypted data being ~~is~~ obtained by decrypting the encrypted data.

[0062] Moreover, a third ~~embodiment~~ aspect of the present invention is a data processing method for processing content data provided by a recording or communication medium. ~~The method being characterized in that said method:~~ generates partial integrity check values as integrity check values for a partial data set. The partial data set contains ~~one or more~~ partial data obtained by a content data-constituting section. ~~into a plurality of parts, and~~ The method collates the generated integrity check values to verify the partial data, and generates an intermediate integrity check value based on a partial integrity check value set data string. The partial integrity check value set contains ~~at least one or more of the partial integrity check values. and~~ The method uses the generated intermediate integrity check value to verify the entirety of the plurality of partial data sets corresponding to the plurality of partial integrity check values using the intermediate integrity check value ~~constituting the partial integrity check value set.~~

[0063] Further, one embodiment of the data processing method according to the present invention is characterized in that the partial integrity check values are ~~is~~ generated by

means of a cryptography process. ~~with a~~ A partial-check-value-generating key is applied thereto, using the partial data to be checked, as a message, ~~and t~~ The intermediate integrity check value is generated by means of thea cryptography process with an general-check-value-generating key applied thereto, ~~using a~~ A partial integrity check value set-data-string to be checked, is used as ~~a~~ the message.

[0064] Further, ~~oneanother~~ embodiment of the data processing method according to the present invention is characterized in that the partial integrity check values ~~areis~~ generated by applying different types of the partial-check-value-generating keys corresponding to ~~generated~~ partial integrity check values.

[0065] ~~AnotherFurther,~~ one embodiment of the data processing method according to the present invention is characterized in that the cryptography process is a DES cryptography process.

[0066] Further, ~~in oneyet another~~ embodiment of the data processing method according to the present invention, ~~is characterized in that~~ the partial integrity check values includeis a message authentication code ~~(MAC)~~ generated in a DES-CBC mode using the partial data to be checked, as a message, ~~and t~~ The intermediate integrity check value is a ~~the~~ message authentication code ~~(MAC)~~ generated in ~~thea~~ DES-CBC mode using ~~thea~~ partial integrity check value set-data-string ~~to be checked,~~ as thea message.

[0067] Further, ~~oneanother~~ embodiment of the data processing method according to the present invention is characterized in that a value generated from saidthe intermediate integrity check value by means of a signature key-applied cryptography process is applied as a collation value for data verification.

[0068] Yet anotherFurther, one embodiment of the data processing method according to the present invention is characterized in that, in order to obtain the collation value for data verification, different signature keys are applied to the cryptography process for the intermediate integrity check value depending on a localization of ~~the~~ content data. The

different signature keys are applied to obtain the collation value for data verification.

[0069] Further, ~~one~~another embodiment of the data processing method according to the present invention ~~is characterized in that~~ further includes selecting and using one of a common signature key common to all entities of a system for executing a data verifying process and ~~or an apparatus-specific signature key specific to each apparatus that executes thea data verifying process.~~ The selecting step is based ~~is selected and used as the signature key depending on the localization of the content data.~~

[0070] Further, ~~one~~another embodiment of the data processing method according to the present invention is characterized in that the partial integrity check values contains at least one ~~or more~~ header section integrity check values generated for intra-header-section data partly constituting data and at least one ~~or more~~ content integrity check values generated for intra-content-section data partly constituting the data. ~~and~~ The method also includes a data verifying process ~~generates~~generating at least one ~~or more~~ header section integrity check values for ~~thea~~ partial data set in the intra-header-section data to execute a collation process. ~~and~~ The method also generates at least one ~~or more~~ content integrity check values for ~~thea~~ partial data set in the intra-content-section data to execute ~~athe~~ collation process. ~~and~~ The method further generates a general integrity check value based on all of the header section integrity check values and the content integrity check values, ~~generated,~~ wherein the general integrity check value is operable to execute thea collation process in order to verify the data.

[0071] Further, ~~one~~Yet another embodiment of the data processing method according to the present invention is characterized in that the partial integrity check values contains at least one ~~or more~~ header section integrity check values generated for intra-header -section data partly constituting data. ~~and~~ The data verifying process ~~comprises~~includes generating at least one ~~or more~~ header section integrity check values for ~~thea~~ partial data set in

the intra-header-section data to execute a collation process.~~7~~
~~and~~ The data verifying process further generates ~~ing~~ a general integrity check value based on the at least~~the one or more~~ header section integrity check values ~~generated~~ and on content block data constituting part of the data.~~7~~ This is done to execute a collation process in order to verify the data.

[0072] Further, ~~one~~another embodiment of the data processing method according to the present invention ~~is characterized by further comprising~~ includes a process for storing, after data verification, storing validated data after verifying the partial data set.

[0073] Further, ~~in~~ one~~another~~ embodiment of the data processing method according to the present invention, ~~is characterized in that if the collation is not established in the process for collating the partial integrity check values, the collation is not established, then control is executed such as to suspend the process for storing validated data in the recording device is suspended.~~

[0074] Further, ~~one~~yet another embodiment of the data processing method according to the present invention ~~is characterized by further comprising~~ a data reproduction process for reproducing data after verifying the partial data verification~~set.~~

[0075] Further, ~~another~~one embodiment of the data processing method according to the present invention includes ~~is characterized in that suspending the reproducing of the data if collating of the partial integrity check values is not established~~if in the process for collating the partial integrity check value, the collation is not established, control is executed such as to suspend the reproduction ~~process executed in the reproduction process section.~~

[0076] Further, one embodiment of the data processing method according to the present invention is characterized ~~wherein~~in that said method collating of the~~collates only the header section partial integrity check values only collates header section~~in the data during the process for collating the partial integrity check values and transmits the data for which collation of the header section integrity check values

has been established, to ~~a~~the reproduction process section for reproduction.

[0077] Moreover, a fourth aspect of the present invention is a data processing method for processing content data provided by a recording or communication medium. ~~The~~the method ~~comprises being characterized in that said method:~~ decrypting encrypted data to be verified to obtain decrypted data; if data to be verified are encrypted, executes executing an arithmetic operation process on the decrypted data to obtain result~~obtained by decrypting the encrypted data;~~; and ~~executes executing~~ a signature key-applied cryptography process ~~on data on arithmetic operation the results obtained by the arithmetic operation,~~ to generate integrity check values for the data to be verified.

[0078] Further, in one embodiment of the data processing method according to the present invention ~~is characterized in that~~ the arithmetic operation process comprises performing an exclusive-OR operation on the decrypted data ~~every~~at predetermined bytes, ~~the decrypted data being obtained by decrypting the encrypted data.~~

[0079] Moreover, a fifth aspect of the present invention is a data verifying value imparting method for a data verifying process. ~~characterized in that said~~ The method includes: ~~imparting~~imparts partial integrity check values as integrity check values for a partial data set. The partial data set contains~~ing one or more~~ partial data obtained by a content data ~~constituting section into a plurality of parts,~~. The method also includes~~and imparts~~imparting to data to be verified, an intermediate integrity check value to data to be verified. The intermediate integrity check value is used to verify a partial integrity check value set ~~data string~~ containing at least one ~~or more~~ of the partial integrity check values.

[0080] Further, one embodiment of the data verifying value imparting method according to the present invention is characterized in that the partial integrity check values ~~is~~are generated by means of a cryptography process with a partial-check-value-generating key applied thereto, using the partial data ~~to be checked, as a message,~~ and ~~the~~ The intermediate

integrity check value is generated by means of thea cryptography process with ~~ana~~ general-check-value-generating key applied thereto, using thea partial integrity check value set ~~data string to be checked,~~ as thea message.

[0081] Further, in one embodiment of the data verifying value imparting method according to the present invention, ~~is characterized in that~~ the partial integrity check values are ~~is~~ generated by applying different types of the partial-check-value-generating keys corresponding to ~~generated~~the partial integrity check values.

[0082] Further, in one embodiment of the data verifying value imparting method according to the present invention, ~~is characterized in that~~ the cryptography process is a DES cryptography process.

[0083] Further, in another~~one~~ embodiment of the data verifying value imparting method according to the present invention, ~~is characterized in that~~ the partial integrity check values include~~is~~ a message authentication code (MAC) generated in a DES-CBC mode using the partial data ~~to be checked,~~ as a message, and the intermediate integrity check value is at~~the~~ message authentication code (MAC) generated in at~~the~~ DES-CBC mode using at~~the~~ partial integrity check value set ~~data string to be checked,~~ as at~~the~~ message.

[0084] Further, in another~~one~~ embodiment of the data verifying value imparting method according to the present invention ~~is characterized in that,~~ a value generated from the intermediate integrity check value by means of a signature key-applied cryptography process is applied as a collation value for data verification.

[0085] Further, in yet another~~one~~ embodiment of the data verifying value imparting method according to the present invention, ~~is characterized in that~~ different signature keys are applied to the cryptography process for the intermediate integrity check value to obtain the collation value, the different signature keys being applied depending on a localization of ~~the content data,~~ ~~to obtain the collation value for data verification.~~

[0086] Further, one embodiment of the data verifying value imparting method according to the present invention further comprising selecting either~~is characterized in that~~ a common signature key ~~common to all entities of a system for executing a data verifying process~~ or an apparatus-specific signature key ~~specific to each apparatus that executes a data verifying process~~ is selected and used as one of the different signature keys depending on the localization of the content data. The common signature key is common to all entities of a system for executing the data verifying process. The apparatus-specific signature key is specific to each apparatus that executes the data verifying process.

[0087] Further, ~~in another~~embodiment of the data verifying value imparting method according to the present invention, ~~is characterized in that~~ the partial integrity check values contains at least one~~or more~~ header section integrity check values for ~~in~~intra-header-section data partly constituting data and at least one~~or more~~ content integrity check values generated for intra-content-section data partly constituting the data. ~~and~~ The method further comprises~~is set so that~~ a generating a general integrity check value is generated~~to verify the data for all the~~ at least one header section integrity check values and the at least one~~the~~ content integrity check values, ~~to verify the data.~~

[0088] Further, one embodiment of the data verifying value imparting method according to the present invention is characterized ~~wherein~~~~in that~~ the partial integrity check values contains at least one~~or more~~ header section integrity check values for intra-header-section data partly constituting data, and the method further comprising generating~~is set so that~~ a a general integrity check value is generated for the at least~~the one or more~~ header section integrity check values and content block data partly constituting the data, ~~to verify the data.~~

[0089] Moreover, a sixth aspect of the present invention is a recording program providing medium recorded with~~for providing~~ a computer program for ~~causing a data verifying process to be executed~~ executing a data verifying process having certain

~~actions. The actions comprise on a computer system to verify that data are valid, the program providing medium being characterized in that the computer program comprises steps of:~~ executing a collation process using partial integrity check values generated as integrity check values for a partial data set containing ~~one or more partial data obtained by dividing data a plurality of parts,~~ and using an intermediate integrity check value based on a partial integrity check value set obtained by combining a plurality of the partial integrity check values together, to verify the entirety of a plurality of partial data sets. The intermediate integrity check value is based on a partial integrity check value set obtained by combining at least some of the partial integrity check values together, and the partial data set corresponding to the plurality of partial integrity check values constituting the partial integrity check value set.

[0090] A seventh aspect of the present invention is a data processing apparatus including an encryption processing section that executes one encryption processing including ~~at least one of data encryption, data decryption, data verification, authentication processing and signature processing and a storage section that stores master keys to generate keys used for the encryption processing.~~ 7 ~~characterized in that~~ The encryption processing section is configured to generate individual keys for executing necessary to execute the encryption processing based on one of the master keys, and identification data of the apparatus or data subject to an encryption processing target apparatus, and data identification data.

[0091] According to another embodiment of the data processing apparatus of the present invention, ~~the data processing apparatus is a data processing apparatus that~~ encryption processing section performs the encryption processing on transfer data via a recoding medium or a communication medium. ~~7~~ ~~characterized in that~~ The storage section stores a distribution key generation master key MKdis for generating a distribution key Kdis. The distribution key Kdis is used for the encryption processing of the transfer

~~data.~~ ~~and the~~ The encryption processing section executes the encryption processing based on said~~the~~ distribution key generation master key MKdis~~stored in the storage section and~~ and a data identifier.7 The data identifier ~~which is~~ includes identification data of the transfer data~~and generates the transfer data distribution key Kdis.~~

[0092] Furthermore, according to another embodiment of the data processing apparatus of the present invention, the data processing apparatus~~is a data processing apparatus that~~ performs authentication processing of an externally connected apparatus~~to/from~~ which data is transferred to or from.~~7~~ ~~characterized in that~~ The~~the~~ storage section stores an authentication key generation master key MKake for generating an authentication key Kake of the externally connected apparatus. and The~~the~~ encryption processing section executes the encryption processing based on the authentication key generation master key MKake~~stored in the storage section and~~ and an identifier of the externally connected apparatus.7 ~~which is~~ The externally connected apparatus identifier including identification data of the externally connected apparatus~~and generates the authentication key Kake of the externally connected apparatus.~~

[0093] Furthermore, according to another embodiment of the data processing apparatus of the present invention, the ~~encryption~~the data processing section~~apparatus is a data processing apparatus that~~ performs the signature processing on data.7 ~~characterized in that the~~ The storage section stores a signature key generation master key MKdev for generating a data processing apparatus signature key Kdev of the data processing apparatus. and the The encryption processing section executes the signature~~encryption~~ processing based on the signature key generation master key MKdev ~~stored in the storage section and an~~ data processing apparatus identifier. The data processing apparatus identifier including~~of the data processing apparatus,~~ which is identification data of said~~the~~ data processing apparatus~~and generates the data processing apparatus signature key Kdev of the data processing apparatus.~~

[0094] Furthermore, according to another embodiment of the data processing apparatus of the present invention, the encryption processing section performs individual key generation processing to that generates an individual keys necessary to execute for executing encryption processing based on the master keys and identification data. ~~of the apparatus or data subject to encryption processing is~~ The encryption processing that uses at least part of identification data of the apparatus or data subject to encryption processing as a message and applies the master keys as the encryption keys.

[0095] Furthermore, according to another embodiment of the data processing apparatus of the present invention, the encryption processing uses ~~is encryption processing using~~ a DES algorithm.

[0096] Furthermore, an eighth aspect of the present invention is a data processing system comprises a plurality of data processing apparatuses, ~~configured by a plurality of data processing apparatuses,~~ characterized in that each of the plurality of data processing apparatuses has a common master key to generate a key used for encryption processing including ~~of~~ at least one of data encryption, data decryption data verification, authentication processing and signature processing (each of said plurality of data processing apparatuses having said common master key), ~~and each of the plurality of data processing apparatuses generates a common individual key for executing~~ necessary to execute the encryption processing based on the master key and identification data. Each of the plurality of data processing apparatuses generating the common individual key of the apparatus or data subject to encryption processing.

[0097] Furthermore, according to another embodiment, ~~of the data processing system of the present invention,~~ further comprises the plurality of data processing apparatuses is configured by a contents data providing apparatus operable to configure the plurality of data processing apparatuses and to supply ~~that supplies~~ contents data. and The system also includes a contents data utilization apparatus that utilizes the contents data. ~~Both both~~ the contents data providing

apparatus and the contents data utilization apparatus have a distribution key generation master key to generate a contents data distribution key. The contents data distribution key is used for encryption processing of circulation contents data between the contents data providing apparatus and the contents data utilization apparatus. ~~The contents data providing apparatus generates a~~ the contents data distribution key based on the distribution key generation master key and a contents identifier. ~~The contents identifier which is an identifier of supplied the contents data and executes encryption processing on the contents data,~~ and the contents data utilization apparatus generates a the contents data distribution key based on the distribution key generation master key and contents identifier, ~~which is an identifier of supplied contents data and executes decryption processing on the contents data.~~

[0098] Furthermore, according to another embodiment of the data processing system of the present invention, the contents data providing apparatus ~~has a plurality of different distribution key generation master keys to generate a plurality of different contents data distribution keys,~~ generates a plurality of different contents data distribution keys based on a the plurality of different distribution key generation master keys and the contents identifier, executes encryption processing using the plurality of different contents data distribution keys ~~generated~~ and generates encryption contents data having ~~of~~ a plurality of types. ~~The and the~~ contents data utilization apparatus has at least one of ~~distribution key generation master key of the~~ plurality of different distribution key generation master keys ~~owned by the contents data providing apparatus~~ and makes decodable only encryption contents data formed by a distribution key generated using ~~the same~~ one of the different distribution key generation master keys that is the same as a the distribution key generation master key owned by an ~~the own~~ apparatus.

[0099] Furthermore, according to another embodiment, ~~of the data processing system of the present invention,~~ further includes ~~each of said plurality of data processing apparatuses stores a same~~ a contents key generation master key to generate

a contents key ~~used for~~applied to contents data encryption processing, of data. The contents key generation master key is stored in each of the plurality of data processing apparatuses. A ~~first processing apparatus A, which is one of said~~the plurality of data processing apparatuses, stores the contents data in a storage medium. The contents data are encrypted by ~~thea contents key generated based on the contents key generation master key and an~~the apparatus identifier of the first one of the plurality of data processing apparatuses~~apparatus A in a storage medium.~~A second one of the plurality of data processing apparatuses ~~apparatus B generates thea contents key based on the same contents key generation master key and the apparatus identifier of the first one of the plurality of data processing apparatuses~~apparatus A and executes decryption processing on the encrypted contents data stored by said data processing apparatus A in the~~said storage medium based on said contents key generated.~~

[0100] Furthermore, according to another embodiment of the data processing system ~~further includes~~of the present invention, the plurality of data processing apparatuses is configured by a host device having an authentication key generation master key and a slave device subject to authentication processing by the host device. The slave device has the authentication key generation master key and a slave device identifier. The authentication key generation master key is used for authentication processing between the host device and said slave device, wherein both the host device and slave device have an authentication key generation master ~~applied to authentication processing between the host device and slave device, the slave device generates an authentication key based on the authentication key generation master key and the slave device identifier.~~The slave device identifier which is the an identifier of the slave device and is stored~~stores in a memory of~~in the slave device. ~~and the~~The host device generates thean authentication key based on the authentication key generation master key and the slave device identifier. The plurality of data processing

apparatuses are configured by the host device and the slave device~~which is the identifier of the slave device and executes authentication processing.~~

[0101] Furthermore, a ninth aspect of the present invention is a data processing method that executes encryption processing including~~of~~ at least one of data encryption, data decryption, data verification, authentication processing and signature processing.7 The data processing method includes~~ing~~ a key generating step of generating individual keys necessary to execute the encryption processing based on master keys to generate the keys used for the encryption processing and identification data of an externally connected~~the~~ apparatus or data subject to encryption processing. and an encryption processing step of The method also includes executing encryption processing based on the individual keys~~the key generated in the key generating step.~~

[0102] Furthermore, according to another embodiment of the data processing method of the present invention, encryption processing~~data processing executed by the data processing method is executed~~encryption processing on transfer data via a storage medium or communication medium.7 the key The step of generating the individual keys includes step is a distribution key generating step of executing encryption processing based on a distribution key generation master key MKdis for generating a distribution key Kdis used for encryption processing of transfer data and a data identifier, which is identification data of the transfer data, and generating a distribution key Kdis of the transfer data.7 The distribution key Kdis is used for encryption processing of the transfer data, and the data identifier includes identification data of the transfer data. and the encryption processing step is a step of executing The encryption processing step includes executing encryption processing on transfer data based on the distribution key Kdis generated in the distribution key generating step.

[0103] Furthermore, according to another embodiment of the data processing method of the present invention, the data encryption processing executed by the data processing method

is authentication processing of ~~thean~~ externally connected apparatus to and ~~/from~~ which data is transferred. The step of the key generating step is an authentication key generating step of individual keys includes executing encryption processing and generating an authentication key Kake. Encryption processing is based on an authentication key generation master key MKake for generating an authentication key Kake of the externally connected apparatus and an externally connected apparatus identifier. The externally connected apparatus identifier includes which is identification data of the externally connected apparatus. and generating the authentication key Kake of the externally connected apparatus. The step of executing and the encryption processing includes step is a step of executing authentication processing of the externally connected apparatus based on the authentication key Kake generated in the authentication key generation step.

[0104] Furthermore, according to another embodiment of the data processing method of the present invention, encryption data processing executed by the data processing apparatus is signature processing on the data. The step of the key generating stepsaid individual keys is includes a signature key generating step of executing signature encryption processing based on a signature key generation master key MKdev and a data processing apparatus identifier, and generating a data processing apparatus signature key Kdev of a data processing apparatus. The signature key generation master key Mkdev is operable to generatefor generating a the data processing apparatus signature key Kdev. The data processing apparatus identifier of the data processing apparatus and a data processing apparatus identifier, which is identification data of the data processing apparatus and generating the data processing apparatus signature key Kdev of the data processing apparatus, and the encryption processing step is a step of includes executing signature processing on the data based on the signature key Kdev generated in the signature key generating step.

[0105] Furthermore, according to another embodiment of the data processing method of the present invention, the step of the key generating step individual keys includes executing is encryption processing that usesusing at least part of the data identification of the externally connected apparatus or the data subject to encryption processing as a message, and applyingapplies the master keys as the encryption keys.

[0106] Furthermore, according to another embodiment of the data processing method of the present invention, the ~~encryption processing is~~ encryption processing usesusing a DES algorithm.

[0107] Furthermore, a tenth aspect of the present invention is ~~a data processing method in a~~ data processing system comprising a contents data providing apparatus that supplies contents data and a contents data utilization apparatus. The contents data providing apparatus is operable to generate a contents data distribution key based on a distribution key generation master key and a contents identifier. The contents identifier is an identifier of contents data and the contents data providing apparatus is operable to execute encryption processing on the contents data. Theand a contents data utilization apparatus that utilizes the contents data. ~~characterized in that the contents data providing apparatus generates a contents data distribution key based on a distribution key generation master key for generating a contents data distribution key used for encryption processing on contents data and a contents identifier, which is the identifier of the provided contents data and executes encryption processing on the contents data, and the~~ The contents data utilization apparatus is operable to generates thea contents data distribution key based on the distribution key generation master key and thea contents identifier, which is the identifier of the provided contents data and executes decryption processing on the contents data.

[0108] Furthermore, according to another embodiment of the data processing ~~systemmethod~~ according to the present invention, the contents data providing apparatus ~~has a plurality of different distribution key generation master keys~~

~~to generate a plurality of different contents data distribution keys,~~ generates a plurality of different contents data distribution keys based on a the plurality of different distribution key generation master keys and the contents identifier, executes encryption processing using the plurality of different contents data distribution keys generated, and generates encryption contents data having of a plurality of types., ~~The and the~~ contents data utilization apparatus has at least one of distribution key generation master key of the plurality of different distribution key generation master keys, ~~owned by the contents data providing apparatus~~ and decrypts only encryption contents data formed by a distribution key generated using the same one of the different distribution key generation master keys that is the same as the a distribution key generation master key owned by an the own apparatus.

[0109] Furthermore, an eleventh aspect of the present invention is a data processing method in a data processing system. The data processing method includes comprising a step of storing, by data processing apparatus A, which is one of the plurality of data processing apparatuses, in a storage medium contents data in a storage medium. The contents data are encrypted using a contents key generated based on a contents key generation master key and are stored by a data processing apparatus A. The contents key is generated based on a contents data generation master key to generate a contents key used for encryption processing of contents data and an the apparatus identifier of the data processing apparatus A., a step of The method also includes generating the same contents key as the contents key by with a different data processing apparatus B based on the same the contents key generation master key as that of the data processing apparatus A and the apparatus identifier of the data processing apparatus A, and a step of The method further includes decrypting the contents data stored in the storage medium using the contents key generated by said data processing apparatus B.

[0110] Furthermore, a twelfth aspect of the present invention is a data processing method in a data processing system including a host device and a slave device subject to

authentication processing by said host device. The data processing method comprising a host device, and a slave device subject to authentication processing by the host device, characterized in that the slave device generates generating an authentication key in the slave device based on an authentication key generation master key to generate an authentication key used for authentication processing between the host device and slave device and a slave device identifier. The authentication key is used for authentication processing between the host device and the slave device. The slave device identifier being which is the an identifier of the slave device. and stores the The method also includes storing the authentication key generated in a memory in the said slave device, and the host device generates generating the an authentication key in the host device based on the authentication key generation master key and the slave device identifier, which is the identifier of the slave device and executes executing authentication processing.

[0111] Furthermore, a thirteenth aspect of the present invention is a recording program providing medium recorded with that supplies a computer program for to execute executing encryption processing having certain actions to perform ef at least one of data encryption, data decryption, data verification, authentication processing and signature processing on a computer system. The actions the computer program comprising a key generating step of generating individual keys necessary to execute the encryption processing based on the master keys to generate the key used for the encryption processing and identification data of the apparatus or data subject to encryption processing, and an encryption processing step of executing encryption processing based on the individual keys generated in the key generating step.

[0112] A fourteenth aspect of the present invention is a data processing apparatus that processes contents data supplied from a storage medium or communication medium. characterized by The apparatus comprising a storage section that stores data processing apparatus identifiers, a list verification section that extracts an illegal device list

included in the contents data and executes collation between entries ~~of the~~ in the illegal device list and the data processing apparatus identifiers stored in the storage section, and a control section that terminates~~stops~~ ~~executing~~ processing of at least ~~either one of reproduction of the contents data or processing of storage in a recording device~~ when the result of the collation ~~processing in the collation processing section~~ shows that the illegal device list includes information that matches the data processing apparatus identifiers.

[0113] According to another embodiment of the data processing apparatus of the present invention, the list verification section comprises an encryption processing section that executes encryption processing on the contents data., ~~and the~~ The encryption processing section verifies the presence or absence of tampering in the illegal device list based on check values of the illegal device list included in the contents data and executes the collation ~~processing~~ only when the verification proves no tampering.

[0114] Furthermore, another embodiment of the data processing apparatus of the present invention further comprises an illegal device list check value generation key., ~~characterized in that~~ The encryption processing section executes encryption processing by applying the illegal device list check value generation key to illegal device list configuration data to be verified, generates illegal device list check values, executes collation between the illegal device list check values and ~~the~~ illegal device list check values included in the contents data and thereby verifies the presence or absence of tampering in the illegal device list.

[0115] Furthermore, according to another embodiment of the data processing apparatus of the present invention, the list verification section comprises an encryption processing section that executes encryption processing on the contents data., The encryption processing section executes decryption processing of an ~~the~~ encrypted illegal device list included in the contents data to produce a decrypted illegal device list,

and executes the ~~collation-processing~~ on the decrypted illegal device list ~~resulting from the decryption processing~~.

Furthermore, according to another embodiment of the data processing apparatus of the present invention, the list verification section comprises an encryption processing section that executes mutual authentication processing with a recording device to ~~from~~ and from which contents data is transferred. ~~The~~ the list verification section extracts the illegal device list included in the contents data and executes collation with the data processing apparatus identifiers stored in the storage section on condition that authentication with the recording device has been established through mutual authentication processing executed by the encryption processing section.

[0116] A fifteenth aspect of the present invention is a data processing method that processes contents data supplied from a storage medium or communication medium. The method comprising ~~a list extracting step of extracting an illegal device list included in the contents data, a collation processing step of~~ executing collation between entries included in the illegal device list ~~extracted in the list extracting step~~ and the data processing apparatus identifiers stored in a storage section in ~~at~~ the data processing apparatus, and

[0117] ~~a step of stopping execution of processing of at least either one of reproduction of the contents data or processing of storage in the recording device when~~ at ~~the~~ result of the ~~collation-processing in the collation-processing~~ step shows that the illegal device list includes information that matches the data processing apparatus identifiers.

[0118] Furthermore, according to another embodiment of the data processing method of the present invention, the data processing method further comprises ~~a verification step of~~ verifying the presence or absence of tampering in the illegal device list based on check values of the illegal device list included in the contents data, and ~~the collation-processing step executes~~ executing collation ~~processing~~ only when the verifying ~~verification~~ step proves no tampering.

[0119] Furthermore, according to another embodiment of the data processing method of the present invention, the ~~verifying~~verification step ~~includes~~comprises ~~a step of~~ executing encryption processing by applying an illegal device list check value generation key to illegal device list configuration data to be verified and generating illegal device list check values, and ~~a step of~~ executing collation between the illegal device list check values ~~generated~~ and the illegal device list check values included in the contents data and thereby verifying the presence or absence of tampering in the illegal device list.

[0120] Furthermore, another embodiment of the data processing method of the present invention further comprises ~~a decrypting step of~~ executing decrypting processing on ~~an~~the encrypted illegal device list included in the contents data to produce a decrypted illegal device list and executing the collation processing step ~~executes the collation processing on~~ on the decrypted illegal device list ~~resulting from the decrypting step.~~

[0121] Furthermore, another embodiment of the data processing method of the present invention further comprises ~~a mutual authentication processing step of~~ executing mutual authentication processing with a recording device ~~to/from~~ which and from which contents data is transferred, ~~and the collation processing step~~ executes Collation ~~collation is performed~~ processing on condition that authentication with the recording device has been established through ~~mutual authentication processing executed by the~~ mutual authentication processing step.

[0122] A sixteenth aspect of the present invention is a contents data generation method comprising that ~~generating~~generates contents data ~~supplied from a storage medium or communication medium~~ to a plurality of recorders ~~/ or a plurality of reproducers.~~ The contents data are supplied from a storage medium or a communication medium. The method also includes storing ~~characterized in that~~ an illegal device list as the header information of the contents data. The illegal device list has whose component data

~~comprising~~~~comprises~~ identifiers of the plurality of recorders/
or the plurality of reproducers, whereby the illegal device
list~~which~~ will be excluded from the use of the contents data
~~is stored as the header information of the contents data.~~

[0123] Furthermore, according to another embodiment of the contents data generation method of the present invention, the illegal device list check values for a tampering check of the illegal device list are also stored as the header information of the contents data.

[0124] Furthermore, according to another embodiment of the contents data generation method of the present invention, the illegal device list is encrypted and stored in the header information of the contents data.

[0125] Furthermore, a seventeenth aspect of the present invention is a recording program supply medium that supplies
recorded with a computer program that allows a computer system
to execute for processing of contents data supplied from a
storage medium or a communication medium. The computer
program comprises~~characterized in that the computer program~~
~~comprises a list extracting step of~~ extracting an illegal
device list included in the contents data, a ~~collation~~
~~processing step of~~ executing collation between entries
included in the illegal device list ~~extracted in the list~~
~~extracting step and the data processing apparatus~~ identifiers
stored in a storage section in the data processing apparatus,
and a ~~step of~~ stopping execution of processing of at
least~~either~~ one of reproduction of the contents data or
processing of storage in a recording device when the result
of the ~~collation processing in the collation processing~~ step
shows that the illegal device list includes information that
matches the data processing identifiers.

[0126] An eighteenth aspect of the present invention is a data processing apparatus that processes contents data supplied via a recording medium or a communication medium. It
~~comprises~~ing an encryption processing section that executes
encryption processing on the contents data, a control section
that executes control over the encryption processing section,
a system common key used for encryption processing ~~in the~~

~~encryption processing section, (which is common to either a~~
plurality of data processing apparatuses using the contents
data), the plurality of data processing apparatuses including
the data processing apparatus. The apparatus also includes
~~at least one of an apparatus-specific key, which is specific~~
~~to the data processing apparatus used for encryption~~
~~processing in the encryption processing section or and an~~
apparatus-specific identifier. The apparatus-specific key is
specific to the data processing apparatus. The apparatus-
specific identifier is used to generate the apparatus-specific
key. ~~characterized in that the~~ The encryption processing
section is configured to perform encryption processing by
applying ~~either one of the system common key and~~ the
apparatus-specific key according to ~~the~~ utilization mode of
the contents data.

[0127] Furthermore, in another embodiment of the data
processing apparatus of the present invention, the encryption
processing section executes encryption processing by applying
~~either one of the system common key and~~ the apparatus-
specific key according to utilization restriction information
included in the contents data.

[0128] Furthermore, another embodiment of the data
processing apparatus of the present invention further
~~includes~~ comprises a recording device for recording the
contents data. ~~characterized in that the encryption~~
~~processing section,~~ When when the utilization mode restricts
usage of ~~imposed with a utilization restriction that the~~
~~contents data should be used only for the own to the data~~
processing apparatus, ~~generates data to be stored in the~~
recording device is generated by executing encryption
processing using the apparatus-specific ~~key on for the contents~~
data. Where the utilization mode permits usage of ~~and in the~~
~~case where the contents data is also made available to an~~ by
at least one of the plurality of data processing apparatuses
other than the own data processing apparatus, the data to be
stored in the recording device is generated by executing
encryption processing using the system common key on the
contents data.

[0129] ~~Furthermore, another~~Another embodiment of the data processing apparatus of the present invention further includes~~comprises~~ a signature key Kdev ~~specific to the data processing apparatus~~ and a system signature key Ksys. The signature key Kdev is specific to the data processing apparatus and said system signature key Ksys is common to thea plurality of data processing apparatuses.~~7 characterized in that the encryption processing section, when~~ When the contents data is stored in a the recording device, the contents data is restricted to use by ~~imposed with a utilization restriction that the contents data should be used only for the own said data processing apparatus.~~7 The encryption processing section generates an apparatus-specific check value through encryption processing by applying saidthe apparatus-specific signature key Kdev to the contents data. ~~Whenand, when the contents data is stored in the recording device, with the contents data alsois made available for use by at least one of the plurality of to an data processing apparatuses other than the own data processing apparatus.~~7 The encryption processing section generates an overall check value through encryption processing by applying the system signature key Ksys to the contents data, and the control section performs control of storing the contents data in the recording device together with either one of the apparatus-specific check value generated by the encryption processing section orand the overall check value together with the contents data in the recording device.

[0130] ~~Furthermore, Yet~~ another embodiment of the data processing apparatus of the present invention further includes~~comprises~~ a signature key Kdev ~~specific to the data processing apparatus~~ and a system signature key Ksys. The signature key Kdev is specific to the data processing apparatus and the system signature key Ksys is common to thea plurality of data processing apparatuses,~~7 characterized in that the encryption processing section, when~~ When the utilization mode restricts usage of contents data imposed with a utilization restriction that the contents data should be used only for the own to the data processing apparatus, and the contents data is reproduced, the encryption processing

section generates an apparatus-specific check value by applying the ~~apparatus-specific~~ signature key Kdev to the contents data and ~~performsexecutes~~ collation processing on the apparatus-specific check value. ~~generated and, when~~ When the utilization mode permits usage of the contents data ~~also made~~ available to ~~anby~~ at least one of the plurality of data processing apparatuses other than the ~~own~~ data processing apparatus, and the contents data is reproduced, the encryption processing section generates an overall check value through ~~encryption processing by~~ applying the system signature key Ksys to the contents data and performs collation processing on the overall check value generated, ~~and the~~ The control section generates reproducible decrypted data by continuing processing of the contents data by the encryption processing section only when collation processing onwith the apparatus-specific check value is established or when the collation with processing on the overall check value is established.

[0131] Furthermore, ~~a~~Another embodiment of the data processing apparatus of the present invention ~~comprises~~ further includes a ~~recording~~ data processing apparatus signature key master key MKdev and a data processing apparatus identifier IDdev, ~~characterized in that the~~ The encryption processing section generates a signature key Kdev as ~~the data processing apparatus specific key~~ through encryption processing based on the recording data processing apparatus signature key master key MKdev and the data processing apparatus identifier IDdev.

[0132] Furthermore, in another embodiment of the data processing apparatus of the present invention, the encryption processing section generates the signature key Kdev through DES encryption processing by applying the recording data processing apparatus signature key master key MKdev to the data processing apparatus identifier IDdev.

[0133] Furthermore, in yet another embodiment of the data processing apparatus of the present invention, the encryption processing section generates an intermediate integrity check value by executing encryption processing on the contents data. ~~The and executes encryption processing~~ includes applying one

~~of the data processing apparatus-apparatus-specific key or and~~
~~the system common key on the intermediate integrity check~~
value.

[0134] Furthermore, in another embodiment of the data processing apparatus of the present invention, the encryption processing section generates a partial integrity check value through encryption processing on a partial data set containing at least one partial data item obtained by dividing the contents data into a plurality of parts and generates ~~an-the~~ intermediate integrity check value through encryption processing on a partial integrity check value set data string containing the partial integrity check value-generated.

[0135] A nineteenth aspect of the present invention is a data processing method for a data processing apparatus that processes contents data supplied via a recording medium or a communication medium, ~~characterized by~~ The method includes selecting either one of, according to a utilization mode of the contents data, an encryption processing key from among an encryption processing system common key common to other data processing apparatuses using the contents data or and an apparatus-specific key,. The encryption processing system common key is common to a plurality of data processing apparatuses using the contents data. The plurality of data processing apparatuses includes the data processing apparatus. The apparatus-specific key which is specific to the data processing apparatus according to the utilization mode of the contents data, and The method also includes executing encryption processing by applying the ~~selected~~ encryption processing key to the contents data.

[0136] Furthermore, in another embodiment of the data processing method of the present invention ~~is characterized in that,~~ the step of encryption processing key selecting the encryption processing key ~~step is a step of~~ includes selecting the encryption processing key according to utilization restriction information contained in the contents data.

[0137] Furthermore, another embodiment of the data processing method of the present invention ~~is characterized in that the processing of storing contents data in the recording~~

~~device, when imposed with a utilization restriction that the contents data should be used only for the own data processing apparatus,~~includes generating data to be stored in the a recording device by executing encryption processing applying using the apparatus-specific key to on the contents data when the utilization mode restricts usage of the contents data to the data processing apparatus., and in the case where the contents data is also made available to an apparatus other than the own data processing apparatus, This embodiment of the method also includes generating the data to be stored in the recording device ~~is generated by~~ executing encryption processing using the encryption processing system common key on the contents data when the utilization mode permits usage of the contents data by at least one of the plurality of data processing apparatuses other than the data processing apparatus.

[0138] Furthermore, another embodiment of the data processing method ~~of the present invention is characterized in that when the contents data is stored in the recording device imposed with a utilization restriction that the contents data should be used only for the own data processing apparatus, the processing of recording contents data in the recording device generates~~includes generating an apparatus-specific check value through encryption processing by applying the an apparatus-specific signature key Kdev to the contents data and, when the contents data is restricted to use by the data processing apparatus and is stored in the recording device. This embodiment also includes when the contents data is stored in the recording device with the contents data also made available to an apparatus other than the own data processing apparatus, generatesgenerating an overall check value through encryption processing ~~by applying the a system signature key Ksys to the contents data, and either one of the apparatus-specific check value generated or the overall check value is stored together with the contents data in the recording device~~when the contents data is available for use by at least one of the plurality of data processing apparatuses other than the data processing apparatus and is stored in the recording

device. The method also includes storing the contents data in the recording device together with one of the apparatus-specific check value and the overall check value.

[0139] Furthermore, in another embodiment of the data processing method of the present invention~~is characterized in that,~~ when reproducing the contents data, the utilization mode restricts usage of~~imposed with a utilization restriction that the contents data should be used only for the own by the data processing apparatus is reproduced,~~ The method further includes the contents data reproducing processing generates~~generating~~ an apparatus-specific check value through encryption processing by applying the~~an~~ apparatus-specific signature key Kdev to the contents data and executes performing collation processing on the apparatus-specific check value~~generated and,~~ when~~When reproducing the contents data imposed with a utilization restriction that the,~~ wherein the utilization mode permits usage of the contents data is also made available to any at least one of the plurality of data processing apparatuses other than the own data processing apparatus is reproduced, In this case, the method generates an overall check value through encryption processing by applying the~~a~~ system signature key Ksys to the contents data and performs collation processing on the overall check value generated, and~~The contents data is reproduced only when collation processing on with the apparatus-specific check value is established or when the collation with processing on the overall check value is established.~~

[0140] Furthermore, another embodiment of the data processing method of the present invention further comprises a ~~step of generating a signature key Kdev as the data processing apparatus specific key through encryption processing based on a data processing apparatus signature key master key MKdev and the a data processing apparatus identifier IDdev.~~

[0141] Furthermore, in another embodiment of the data processing method of the present invention~~is characterized in that,~~ the signature key Kdev generating step is a step of~~generating the signature key Kdev through~~ includes DES encryption processing by applying the data processing

apparatus signature key master key MKdev to the data processing apparatus identifier IDdev.

[0142] Furthermore, yet another embodiment of the data processing method of the present invention further comprises a ~~step of~~ generating an intermediate integrity check value by executing encryption processing on the contents data, ~~characterized by executing.~~ The encryption processing includes applying one of the data processing apparatus-apparatus-specific key ~~or~~ and the system common key to the intermediate integrity check value.

[0143] Furthermore, another embodiment of the data processing method of the present invention ~~is characterized by~~ further includes generating a partial integrity check value through encryption processing on a partial data set containing at least one partial data item obtained by dividing the contents data into a plurality of parts. This embodiment also includes and ~~generating an~~ the intermediate integrity check value through encryption processing on a partial integrity check value set data string containing the partial integrity check value ~~generated.~~

[0144] A twentieth aspect of the present invention is a ~~program supply~~ recording medium that supplies recorded with a computer program for a data processing apparatus. The computer program ~~allowing a computer system to execute data processing that processes contents data supplied via a recording medium or a communication medium,~~ and the The computer program comprises the steps of selecting, according to a utilization mode of the contents data, a key from among either an encryption processing key, an encryption processing system common key common to other data processing apparatuses using the contents data ~~or~~ and an apparatus-specific key, . The encryption processing system common key is common to a plurality of data processing apparatuses using the contents data. The plurality of data processing apparatuses including the data processing apparatus. The apparatus-specific key which is specific to the data processing apparatus according to the utilization mode of the contents data, The computer program also and ~~executing~~ executes encryption processing by

applying the ~~selected encryption processing~~ key to the contents data.

[0145] A twenty first aspect of the present invention is a data processing apparatus that processes contents data supplied via a recording medium or a communication medium, ~~comprising.~~ The data processing apparatus comprises an encryption processing section that executes encryption processing on the contents data, and a control section that executes control over the encryption processing section, ~~characterized in that.~~ The encryption processing section is configured to generate a contents check value in units of contents block data to be verified included in the contents data, and to execute collation on the contents check value generated and thereby execute verification processing on the validity of each of said units of contents block data ~~in the data.~~

[0146] Furthermore, another embodiment of the data processing apparatus of the present invention ~~comprises~~ further includes a contents check value generation key ~~and characterized in that,~~ wherein the encryption processing section generates a contents intermediate value based on the contents block data to be verified and generates a contents check value by ~~executing encryption processing~~ applying the contents check value generation key to the contents intermediate value.

[0147] Furthermore, in another embodiment of the data processing apparatus of the present invention ~~is characterized in that,~~ when the contents block data ~~to be verified~~ is encrypted, the encryption processing section generates ~~a~~ the contents intermediate value by executing predetermined operation processing on an entire decrypted statement in units of a predetermined number of bytes. The entire decrypted statement is obtained through by decryption processing of the contents block data in units of a predetermined number of bytes, ~~and.~~ when ~~When~~ the contents block data ~~to be verified~~ is not encrypted, the encryption processing system generates a the contents intermediate value by executing predetermined

operation processing on the ~~entire~~ contents block data in units of a predetermined number of bytes.

[0148] Furthermore, in yet another embodiment of the data processing apparatus of the present invention ~~is characterized in that,~~ the predetermined operation processing ~~applied in the intermediate integrity check value generation processing by the encryption processing section~~ is an exclusive-OR operation.

[0149] Furthermore, in another embodiment of the data processing apparatus of the present invention ~~is characterized in that,~~ the encryption processing section has an encryption processing configuration in a CBC mode and the decryption processing ~~applied to the content intermediate value generation processing when the contents block data to be verified~~ is decryption processing in the CBC mode.

[0150] Furthermore, in another embodiment of the data processing apparatus of the present invention ~~is characterized in that,~~ the encryption processing configuration in the CBC mode ~~of the encryption processing section~~ is a configuration in which common key encryption processing is applied a plurality of times only to part of a message string ~~to be processed~~.

[0151] Furthermore, in yet another embodiment of the data processing apparatus of the present invention ~~is characterized in that,~~ when the contents block data contains a plurality of parts and ~~some~~ a portion of the plurality of parts included in the contents block data ~~are~~ is to be verified, the encryption processing section generates a the contents check value based on the parts portion to be verified, and executes collation processing on the contents check value ~~generated and thereby executes verification processing on the validity in units of content block data in the data~~.

[0152] Furthermore, in an alternative another embodiment of the data processing apparatus of the present invention ~~is characterized in that,~~ when the ~~contents block data~~ contains a plurality of parts and it is one part that needs to be verified, the portion is encrypted, the encryption processing section generates a the contents check value by ~~executing encryption processing applying the~~ a contents check value

generation key to a value obtained by carrying out an exclusive-OR in units of a predetermined number of bytes on ~~the~~ an entire decrypted statement, which is obtained by decryption processing of parts to be verified in the case where the parts to be verified is encrypted the portion, ~~and~~ When the portion is not encrypted, the encryption processing section generates a ~~the~~ contents check value by executing encryption processing applying the contents check value generation key to a ~~the~~ value obtained by carrying out an exclusive-OR in units of a predetermined number of bytes on the entire part to be verified in the case where the parts to be verified is not encrypted.

[0153] Furthermore, another embodiment of the data processing apparatus of the present invention is characterized in that when the ~~contents block data contains a plurality of parts and it is a portion of the plurality of parts that needs to be verified,~~ the encryption processing section ~~uses, as a contents check value, the result obtained by executing encryption processing~~ applies a contents check value generation key to the portion of the plurality of parts to obtain a parts check value. The encryption processing section also applying applies the contents check value generation key to link data of a ~~the~~ parts check value to obtained by executing encryption processing applying a result, and use the result as the contents check value generation key to each part.

[0154] Furthermore, in another embodiment of the data processing apparatus of the present invention ~~is characterized in that,~~ the encryption processing section further comprises a recording device for storing the contents data containing the units of contents block data whose validity has been verified.

[0155] Furthermore, another embodiment of the data processing apparatus of the present invention is characterized in that, when collation processing is not established in the collation processing executed on a ~~the~~ contents check value in the encryption processing section, the control section stops the storage in the recording device.

[0156] Furthermore, in yet another embodiment of the data processing apparatus of the present invention ~~is characterized~~

~~in that~~ the encryption processing section further comprises a reproduction processing section for reproducing data whose validity has been verified.

[0157] Furthermore, in another embodiment of the data processing apparatus of the present invention ~~is characterized in that,~~ when collation processing is not established ~~in the collation processing executed on a the contents check value in the encryption processing section,~~ the control section stops the reproduction processing in the reproduction processing section.

[0158] A twenty second aspect of the present invention is a data processing method that processes contents data supplied via a recording medium or a communication medium, ~~characterized by.~~ The method includes generating a contents check value in units of contents block data ~~to be verified~~ included in the contents data, and executing collation processing on the contents check value ~~generated~~ and thereby ~~executing~~ executes verification processing ~~on as to~~ the validity ~~in of~~ the units of contents block data ~~in the data.~~

[0159] Furthermore, another embodiment of the data processing method of the present invention ~~is characterized by~~ ~~generating~~ generates a contents intermediate value based on the contents block data to be verified, and generating generates a contents check value by executing encryption processing by applying the contents check value generation key to the contents intermediate ~~value generated.~~

[0160] Furthermore, in another embodiment of the data processing method of the present invention ~~is characterized by~~ ~~generating,~~ when the contents block data ~~to be verified~~ is encrypted, a contents intermediate value is generated by executing predetermined operation processing on an entire decrypted statement in units of a predetermined number of bytes. The entire decrypted statement is obtained through ~~by~~ decryption processing of the contents block data ~~in units of a predetermined number of bytes, and generating,~~ when ~~When~~ the contents block data ~~to be verified~~ is not encrypted, ~~a the~~ contents intermediate value is generated by executing the

predetermined operation processing on the ~~entire~~ contents block data in the units of ~~a~~ the predetermined number of bytes.

[0161] Furthermore, in another embodiment of the data processing method of the present invention ~~is characterized in that,~~ the predetermined operation processing ~~applied in the intermediate integrity check value generation processing~~ is an exclusive-OR operation.

[0162] Furthermore, in yet another embodiment of the data processing method of the present invention ~~is characterized in that in,~~ the ~~contents intermediate value generation processing,~~ the decryption processing ~~applied to the content intermediate value generation processing when the contents block data to be verified is encrypted~~ is decryption processing in CBC mode.

[0163] Furthermore, in another embodiment of the data processing method of the present invention ~~is characterized in that,~~ in the step of decryption processing configuration in the CBC mode, common key encryption processing is applied a plurality of times only to part of a message string ~~to be processed.~~

[0164] Furthermore, in yet another embodiment of the data processing method of the present invention ~~is characterized by generating,~~ when the contents block data contains a plurality of parts and ~~some~~ a portion of the plurality of parts included in the contents block data are is to be verified, ~~a~~ the contents check value is generated based on the parts portion to be verified prior to executing the, ~~executing~~ collation processing on the contents check value ~~generated and thereby executing verification processing on the validity in units of content block data in the data.~~

[0165] Furthermore, in another embodiment of the data processing method of the present invention ~~is characterized by,~~ when the portion is encrypted, the method includes performing decryption processing on the portion to obtain an entire decrypted statement, carrying out an exclusive-OR operation in units of a predetermined number of bytes on the entire decrypted statement, and generating ~~when the contents block data contains a plurality of parts and it is one part that needs to be verified,~~ the contents check value by executing

~~encryption processing applying the a contents check value generation key to a value obtained by carrying out an the exclusive-OR operation. When the portion is not encrypted, the method includes in units of a predetermined number of bytes on the entire decrypted statement obtained by decryption processing of parts to be verified in the case where the parts to be verified is encrypted, and generating a the contents check value by executing encryption processing applying the contents check value generation key to a the value obtained by carrying out an exclusive-OR in units of a predetermined number of bytes on the entire part to be verified in the case where the part to be verified is not encrypted.~~

[0166] Furthermore, another embodiment of the data processing method of the present invention ~~is characterized by using, when the contents block data contains a plurality of parts and it is a plurality of parts that needs to be verified, as a contents check value, the result obtained by executing encryption processing further applying the contents check value generation key to link data of a parts check value obtained by executing encryption processing applying the contents check value generation key to each part~~ includes: applying a contents check value generation key to each of the plurality of parts to obtain a parts check value; further applying the contents check value generation key to link data of the parts check value to obtain a result; and using the result as the contents check value.

[0167] Furthermore, another embodiment of the data processing method of the present invention ~~further comprises a step of~~ includes storing the contents data containing said units of contents block data whose validity has been verified.

[0168] Furthermore, yet another embodiment of the data processing method of the present invention ~~is characterized in that~~ further includes stopping the storing of the contents data when the collation processing is not established in the collation processing executed on a the contents check value, the control section stops storage in the recording device.

[0169] Furthermore, another embodiment of the data processing method of the present invention ~~further comprises a~~

~~step of~~includes reproducing data whose validity has been verified.

[0170] Furthermore, another embodiment of the data processing method of the present invention ~~is characterized by further includes stopping the reproduction processing when the collation processing is not established executed in the collation processing on a the contents check value.~~

[0171] A twenty third aspect of the present invention is a contents data verification value assignment method for contents data verification processing, ~~characterized by. The method includes first generating a contents check value in units of contents block data to be verified. The contents block data are included in the contents data, . The method also includes assigning the contents check value generated to the contents data containing the contents block data to be verified.~~

[0172] Furthermore, in another embodiment of the contents data verification value assignment method of the present invention ~~is characterized in that,~~ the contents check value is generated through encryption processing by applying the a contents check value generation key using the contents block data ~~to be checked as a message.~~

[0173] Furthermore, in yet another embodiment of the contents data verification value assignment method of the present invention ~~is characterized in that,~~ the contents check value is generated by generating a contents intermediate value based on the contents block data ~~to be verified and executing encryption processing applying the a~~ contents check value generation key to the contents intermediate value.

[0174] Furthermore, in another embodiment of the contents data verification value assignment method of the present invention ~~is characterized in that,~~ the contents check value is generated by executing encryption processing on the contents block data in a CBC mode on the contents block data ~~to be verified.~~

[0175] Furthermore, in yet another embodiment of the contents data verification value assignment method of the present invention ~~is characterized in that,~~ the encryption

~~processing configuration in CBC mode is a configuration in which common key encryption processing is applied a plurality of times only to part of a message string to be processed.~~

[0176] Furthermore, in another embodiment of the contents data verification value assignment method of the present invention is characterized by generating, when the contents block data contains a plurality of parts and some parts included in the contents block data area portion of the plurality of parts is to be verified, the method further comprises generating thea contents check value based on the parts to be verifiedportion and assigning the contents check value generated to the contents data containing the content block data to be verified.

[0177] Furthermore, another embodiment of the contents data verification value assignment method of the present invention ~~is characterized by generating,~~ further includes, when the portion is encrypted: performing decryption processing of the portion to obtain an entire decrypted statement; carrying out an exclusive-OR operation in units of a predetermined number of bytes on the entire decrypted statement to obtain a value; and generating the contents check value by applying a contents check value generation key to the value. When the portion is not encrypted, the method further includes generating the contents check value by applying the contents check value generation key to the value ~~when the contents block data contains a plurality of parts and it is one part that needs to be verified, a contents check value by executing encryption processing applying the contents check value generation key to a value obtained by carrying out an exclusive-OR in units of a predetermined number of bytes on the entire decrypted statement obtained by decryption processing of parts to be verified in the case where the parts to be verified is encrypted, generating a contents check value by executing encryption processing applying the contents check value generation key to a value obtained by carrying out an exclusive-OR in units of a predetermined number of bytes on the entire part to be verified in the case where the parts to be verified is not encrypted and assigning the contents check~~

~~value generated to the contents data containing the contents block data to be verified.~~

[0178] ~~Furthermore, Yet another embodiment of the contents data verification value assignment method of the present invention is characterized by using further includes: applying a contents check value generation key to each of the plurality of parts to obtain a parts check value; further applying the contents check value generation key to link data of the parts check value to obtain a result; and using the result as the contents check value, when the contents block data contains a plurality of parts and it is a plurality of parts that needs to be verified, as a contents check value, the result obtained by executing encryption processing further applying the contents check value generation key to link data of a parts check value obtained by executing encryption processing applying the contents check value generation key to each part and assigning the contents check value generated to contents data containing the contents block data to be verified.~~

[0179] ~~A twenty fourth aspect of the present invention is a program supplyrecording medium that suppliesrecorded with a computer program to executefor executing data processing on contents data supplied via a recording medium or a communication medium, . with tThe computer program comprising comprises a step of generating a contents check value in units of contents block data to be verified included in the contents data, and a step of executing collation processing on the contents check value generated and, thereby executing verification processing on as to the validity in of the units of contents block data in the data.~~

[0180] ~~A twenty fifth aspect of the present invention is a data processing apparatus for executing proecessing for generating storing data with respect to a reecording device for recording of content data, . The content data includes which has a plurality of content blocks in which at least a part of the blocks are enerypted and a header section. At least a part of the plurality of content blocks is encrypted. The header section is operable to storing store information on the contents blocks, which is characterized in that. The content~~

data is structured by encryption key data Kdis[Kcon] stored in the header section. The encryption key data Kdis[Kcon] is formed by applying an encryption key Kdis to an encryption key Kcon.

~~in the case in which content data to be an object of storage in the recording device is structured by data stored in the header section, which is an encryption key data Kdis[Kcon] that is an encryption key Kcon of the content block applied encryption processing by an encryption key Kdis,~~

[0181] ~~the~~ The data processing apparatus has ~~comprises a structure~~ means ~~for executing processing for taking out~~ removing ~~the encryption key data Kdis[Kcon] from the header section; means for and~~ executing decryption processing on the encryption key data Kdis[Kcon] to generate decryption data Kcon, ~~;~~ means for generating a new encryption key data Kstr[Kcon] that is by applied ~~applying encryption processing by an encryption key Kstr to the decryption data Kcon; means for and storing the new encryption key data Kstr[Kcon] in the header section of the content data;~~ and means for applying a different encryption key Kstr to the generated decryption data Kcon to execute encryption processing.

[0182] A twenty sixth aspect of the present invention is a data processing apparatus for ~~executing processing for generating storing data with respect to a recording device of for recording content data,~~ The content data includes ~~which has a plurality of content blocks in which at least a part of the blocks are encrypted and a header section. At least a part of the plurality of content blocks is encrypted. The header section is operable to storing~~ store information on the contents blocks, ~~The plurality of content blocks is composed of contents encrypted by an encryption key Kblc and encryption key data Kcon[Kblc]. The encryption key data Kcon[Kblc] is formed by applying an encryption key Kcon to the encryption key Kblc. The plurality of content blocks have a structure in which encryption key data Kdis[Kcon] is stored in the header section. The encryption key data Kdis[Kcon] is formed by applying an encryption key Kdis to the encryption key Kcon. The data processing apparatus comprises: ~~which is~~~~

~~characterized in that: in the case in which the content block included in content data to be an object of storage with respect to the recording device is composed of contents encrypted by an encryption key Kblc and encryption key data Keon[Kblc] that is encrypted by the encryption key Keon, and has a structure in which encryption key data Kdis[Keon] that is the encryption key Keon applied encryption processing by an encryption key Kdis is stored in the header section, the data processing apparatus has a structure for executing processing for taking out means for removing the encryption key data Kdis[Kcon] from the header section; and means for executing decryption processing on the encryption key data Kdis[Kcon] to generate decryption data Kcon; means for generating an new encryption key data Kstr[Kcon] that is applied by applying encryption processing by an encryption key Kstr to the decryption data Kcon; and means for storing the new encryption key data Kstr[Kcon] in the header section of the content data; and means for applying a different encryption key Kstr to the generated decryption data Kcon to execute the encryption processing.~~

[0183] In addition, a twenty seventh aspect of the present invention is a data processing apparatus ~~for executing processing for generating storing data with respect to a recording device of~~ for recording content data,. The content data includes which has a plurality of content blocks in which at least a part of the blocks are encrypted and a header section. At least a part of the plurality of content blocks is encrypted. The header section is operable to storing store information on the contents blocks,. The plurality of content blocks are composed of contents encrypted by an encryption key Kblc and encryption key data Kdis[Kblc]. The encryption key data Kdis[Kblc] is formed by applying an encryption key Kdis to the encryption key Kblc. The data processing apparatus comprises~~characterized in that: in the case in which the content block included in content data to be an object of storage with respect to the recording device is composed of contents encrypted by an encryption key Kblc and encryption key data Kdis[Kblc] that is encrypted by the encryption key~~

~~Kdis, the data processing apparatus has a structure for~~means
~~for removing~~executing processing for taking out the encryption
key data Kdis[Kblc] from the a content block section; and
means for executing decryption processing of the encryption
key data Kdis[Kblc] to generate decryption data Kblc; means
for generating an encryption key data Kstr[Kblc] that is
applied encryption processing by applying an encryption key
Kstr and to the decryption data Kblc; means for storing the
encryption key data Kstr[Kblc] in a the contents block
section; and means for applying a different encryption key
Kstr to the generated decryption data Kblc to execute the
encryption processing.

[0184] ~~In addition, a~~A twenty eighth aspect of the present
invention is a content data generating method for generating
content data, which ~~The method comprises:~~ coupling a
plurality of content blocks ~~composed of data including at~~
least ~~any one of voice information, image information and~~
program data; applying encryption processing to at least a
part of the content blocks ~~included in the plurality of~~
~~content blocks by using~~ an encryption key Kcon; generating
encryption key data Kdis[Kcon] ~~that is the encryption key Kcon~~
~~applied encryption processing by an encryption key Kdis by~~
applying an encryption key Kdis to the encryption key Kcon;
~~and storing the encryption key Kdis in a header section of the~~
content data; and generating the content data including the
plurality of content blocks and the header section.

[0185] In addition, an embodiment of the content data
generating method of the present invention ~~is characterized by~~
further ~~comprising~~ includes processing for generating block
information that storing stores information including at least
one of identification information of on the content data, data
length of content data, usage policy information including a
data types length of the content data and a data type of the
content data, a data length of at least one of the content
blocks, and a presence or absence of encryption processing,
~~and The method also includes storing the block information in~~
the header section.

[0186] In addition, ~~an another~~ embodiment of the content data generating method of the present invention ~~is characterized in that, the content data generating method comprises processing for the method further includes~~ generating a part check value based on a ~~part portion~~ of information composing the header section, ~~and storing the part check value in the header section, and further generating a total check value based on the part check value and storing the total check value in the header section.~~

[0187] In addition, ~~an yet another~~ embodiment of the content data generating method of the present invention ~~is characterized in that, the steps of generation generating processing of the part check value and the generation generating processing of the total check value are executed by applies applying and executes a DES encryption processing algorithm with using data to be an object of checked as a message and using a check value generating key as an encryption key.~~

[0188] In addition, an embodiment of the content data generating method of the present invention ~~is characterized in that the content data generating method further includes applies applying encryption processing to the block information by applying the encryption key Kdis to an the encryption key Kbit, and stores storing the encryption key data Kdis[Kbit] that is the encryption key Kbit generated by the encryption key Kdis in the header section.~~

[0189] In addition, ~~an in another~~ embodiment of the content data generating method of the present invention ~~is characterized in that, each block of the plurality of content blocks in the content block is generated as a common fixed data length.~~

[0190] In addition, ~~in yet an another~~ embodiment of the content data generating method of the present invention ~~is characterized in that, each block of the plurality of content blocks in the content block is generated with a structure in which an encryption data section and a non-encryption section are arranged regularly.~~

[0191] A twenty ninth aspect of the present invention is ~~the a~~ content data generating method for generating content data ~~which comprises:~~. The method includes first coupling a plurality of content blocks each including at least any one of voice information, image information and program data;. The method then composing composes at least a part of the plurality of content blocks by an eneryption data section that is data including at least any one of voice information, image information and program dataapplying an encryption key Kcon to ~~by an encryption key Kblc, and to obtain a set of encryption key data Kcon[Kblc] that is the eneryption key Kble of the eneryption data section applied eneryption processing by an eneryption key Keon;~~. The method generating generates encryption key data Kdis[Kcon] that is theby applying an encryption key Kdis to the encryption key Kcon~~applied eneryption processing by an eneryption key Kdis.~~ The method and storing stores the generated the encryption key data Kdis[Kcon] in a header of the content data;. The method also and generating generates the content data including a the plurality of content blocks and a the header section.

[0192] A thirtieth aspect of the present invention is ~~the a~~ content data generating method for generating content data. ~~which~~The method comprises: coupling a plurality of content blocks each including at least any one of voice information, image information and program data; composing at least a part of the plurality of content blocks by an eneryption data sectionapplying an encryption key Kdis to an encryption key Kblc to obtain encryption key data Kdis[Kblc] that is data including at least one of voice information, image information and program data by an eneryption key Kble, and a set of eneryption key data Kdis[Kble] that is the eneryption key Kble of the eneryption data section applied eneryption processing by an eneryption key Kdis; and generating the content data including a the plurality of content blocks and a header section of the content data.

[0193] A thirty first aspect of the present invention is a data processing method ~~for executing processing for storing content data~~ in a recording device. The content data having

has a plurality of content blocks in which at least a part of blocks are encrypted, and a header section. At least a part of the plurality of content blocks are encrypted. The header section is operable to store in which information on the plurality of content blocks is stored,. The content data is structured by encryption key data Kdis[Kcon] stored in the header section. The encryption key data Kdis[Kcon] is formed by applying an encryption key Kdis to an encryption key Kcon. ~~which~~ The method comprises: in the case in which content data to be an object of storage in the recording device is structured by data stored in the header section, which is an encryption key data Kdis[Keon] that is an encryption key Keon of the content block applied encryption processing by an encryption key Kdis, taking out removing the encryption key data Kdis[Kcon] from the header section; and executing decryption processing on the encryption key data Kdis[Kcon] to generate decryption data Kcon; generating a new encryption key data Kstr[Kcon] that is applied encryption processing by an encryption key Kstr by applying a different an encryption key Kstr to the generated decryption data Kcon to execute encryption processing; and storing the generated new encryption key data Kstr[Kcon] in a the header section of the content data,; and storing the header section in the recording device together with the plurality of content blocks.

[0194] A thirty second aspect of the present invention is a data processing method ~~for executing processing for storing content data in a recording device.~~ The content data having has a plurality of content blocks in which at least a part of blocks are encrypted, and a header section. At least a part of the plurality of content blocks are encrypted. The header section is operable to store in which information on the plurality of content blocks is stored,. The plurality of content blocks are composed of contents encrypted by an encryption key Kblc and encryption key data Kcon[Kblc]. The encryption key data Kcon[Kblc] is formed by applying an encryption key Kcon to the encryption key Kblc. The plurality of content blocks has a structure in which encryption key data Kdis[Kcon] is stored in the header section. The encryption key

data Kdis[Kcon] is formed by applying an encryption key Kdis to the encryption key Kcon. which The method comprises: in the case in which the content block included in content data to be an object of storage with respect to the recording device is composed of contents encrypted by an encryption key Kblc and encryption key data Kcon[Kblc] that is encrypted by the encryption key Kcon, and has a structure in which encryption key data Kdis[Kcon] that is the encryption key Kcon applied encryption processing by an encryption key Kdis is stored in the header section, taking out removing the encryption key data Kdis[Kcon] from the header section; and executing decryption processing on the encryption key data Kdis[Kcon] to generate decryption data Kcon; generating a new encryption key data Kstr[Kcon] that is applied encryption processing by an encryption key Kstr by applying a different an encryption key Kstr to the generated decryption data Kcon to execute decryption processing; and storing the new generated encryption key data Kstr[Kcon] in a the header section of the content data; and storing the header section in the recording device together with the plurality of content blocks.

[0195] A thirty third aspect of the present invention is a data processing method ~~for executing processing~~ for storing content data in a recording device. The content data having have a plurality of content blocks in which at least a part of blocks are encrypted, and a header section. At least a part of the plurality of content blocks are encrypted. The header section is operable to store in which information on the plurality of content blocks is stored, . The plurality of content blocks are composed of contents encrypted by an encryption key Kblc and encryption key data Kdis[Kblc]. The encryption key data Kdis[Kblc] is formed by applying an encryption key Kdis to the encryption key Kblc. which The method comprises: in the case in which the content block included in content data to be an object of storage with respect to the recording device is composed of contents encrypted by an encryption key Kblc and encryption key data Kdis[Kblc] that is encrypted by the encryption key Kdis, taking out removing the encryption key data Kdis[Kblc] from the

~~a content block section and; executing decryption processing of the encryption key data Kdis[Kblc] to generate decryption data Kblc; generating an encryption key data Kstr[Kblc] that is applied encryption processing by an encryption key Kstr by applying a different an encryption key Kstr to the generated decryption data Kblc to execute decryption processing; and storing the generated encryption key data Kstr[Kblc] in a the content block section,; and storing the content block section in the recording device together with the plurality of content blocks.~~

[0196] A thirty fourth aspect of the present invention is a ~~program providing recording medium for providing recorded with a computer program causing generation processing of for generating~~ storing data with respect to a ~~recording device of for recording content data,.~~ The content data ~~which has includes~~ a plurality of content blocks in which at least a part of the blocks are encrypted and a header section. At least a part of the plurality of content blocks are encrypted and the header section is operable to ~~storing~~ store information on the contents blocks,.
The content data is structured by encryption key data Kdis[Kcon] stored in the header section. The encryption key data Kdis[Kcon] is formed by applying an encryption key Kdis to an encryption key Kcon. ~~to be executed on a computer system, which is characterized in that: t~~The computer program comprises: in the case in which content data to be an object of storage in the recording device is structured by data stored in the header section, which is an encryption key data Kdis[Kcon] that is an encryption key Keon of the content block applied encryption processing by an encryption key Kdis, a step of taking out ~~removing~~ the encryption key data Kdis[Kcon] from the header section ~~and; executing decryption processing on the encryption key data Kdis[Kcon] to generate decryption data Kcon; generating a new encryption key data Kstr[Kcon] that is applied encryption processing by an encryption key Kstr by applying a different an encryption key Kstr to the generated decryption data Kcon to execute decryption processing; and~~

storing the ~~generated new~~ encryption key data Kstr[Kcon] in a ~~the header section of the content data.~~

[0197] A thirty fifth aspect of the present invention is a data processing apparatus for ~~performing reproduction processing of reproducing~~ content data. The content data includes compressed contents and an expansion processing program of the compressed contents, and is provided by a storage medium or a communication medium, which is characterized by. The data processing apparatus ~~comprising~~includes a content data analyzing section for executing content data analysis of ~~the content data including~~ compressed contents and ~~an the~~ expansion processing program of the compressed contents. The content data analyzing section is operable to, and executing extraction processing ~~extract~~ of the compressed contents and the expansion processing program from the content data; —. The apparatus also includes ~~and an~~ expansion processing section for executing expansion processing of the content data ~~included in the content data~~ using an expansion processing program ~~included in the content data obtained as a result of the analysis of the content data analyzing section.~~

[0198] In addition, in one embodiment of the data processing apparatus of the present invention, the data processing apparatus ~~is characterized by~~ further ~~comprising~~includes a data storing section for storing the compressed contents ~~that are extracted by the content data analyzing section,~~ and a program storing section for storing the expansion processing program ~~extracted by the content data analyzing section, and characterized in that~~ the The expansion processing section has a configuration for executing the expansion processing with respect to the compressed contents ~~stored in the data storing section by applying the expansion processing program stored in the program storing section to the compressed contents.~~

[0199] In addition, in one embodiment of the data processing apparatus of the present invention, ~~the data processing apparatus is characterized in that~~ the contents data analyzing section has a configuration for obtaining a

configuration information of the content data based on header information included in the content data, and the content data analyzing section is operable to performing analysis of the content data.

[0200] In addition, in one embodiment of the data processing apparatus of the present invention, ~~the data processing apparatus is characterized in that reproduction priority information of the compressed contents is included in the header information and, if~~ If there are a plurality of compressed contents ~~that is objects of expansion processing in the expansion processing section,~~ the expansion processing section has a configuration for sequentially executing content expansion processing in accordance with ~~the priority based on the reproduction priority information in the header information obtained in the content data analyzing section.~~

[0201] In addition, in one embodiment of the data processing apparatus of the present invention, the data processing apparatus ~~is characterized by further comprising~~ includes displaying means for displaying information of the compressed contents ~~that are objects of expansion processing;~~ and inputting means for inputting reproduction contents identification data selected from the ~~content information displayed on the displaying means, and characterized in that~~ The expansion processing section has a configuration for executing expansion processing of the compressed contents corresponding to the identification data based on the reproduction contents identification data inputted from the inputting means.

[0202] In addition, a thirty sixth aspect of the present invention is a data processing apparatus for ~~performing reproduction processing of~~ reproducing content data. The content data includes one of compressed contents and an expansion processing program. The content data is provided by a storage medium or a communication medium, which is characterized by comprising: The apparatus includes a content data analyzing section for receiving the content data including either compressed contents or expansion processing program. The content data analyzing section is operable to

distinguishing whether the content data ~~has the~~ includes the compressed contents or the expansion processing program from header information included in the received content data ~~and, at the same time, . if~~ If the content data has includes the compressed contents, the content data analyzing section is operable to analyze ~~obtaining~~ a type of a compressing processing program applied to the compressed contents from the header information ~~of the content data, and . if~~ If the content data has includes the expansion processing program, the content data analyzing section is operable to analyze ~~obtaining~~ a type of ~~the~~ expansion processing program from the header information ~~of the content data, .~~ The apparatus also includes an expansion processing section for executing expansion processing of the compressed contents, ~~characterized in that . the~~ The expansion processing section has a configuration for selecting an a specific expansion processing program applicable to the type of ~~the~~ compression processing program of ~~the compressed contents analyzed by the content data analyzing section, and being operable to executing~~ execute the expansion processing by using the selected specific expansion processing program.

[0203] In addition, in one embodiment of the data processing apparatus of the present invention, the data processing apparatus ~~is characterized by further comprising~~ includes a data storing section for storing the compressed contents ~~that are extracted~~ analyzed by the content data analyzing section, ~~and a program storing section for storing the specific expansion processing program extracted by the content data analyzing section, and characterized in that, wherein~~ the expansion processing section has a configuration for executing the expansion processing ~~with respect to the compressed contents stored in the data storing section by applying the specific expansion processing program stored in the program storing section to the compressed contents.~~

[0204] In addition, in one embodiment of the data processing apparatus of the present invention, the data

processing apparatus ~~is characterized~~ further includes ~~in that~~ reproduction priority information ~~of~~ associated with the compressed contents. The reproduction priority information is included in the header information ~~and, if~~ If there are a plurality of compressed contents ~~that is objects of expansion processing, content,~~ the expansion processing in the expansion processing section has a configuration for sequentially executing ~~content~~ the expansion processing in accordance with the ~~priority based on the reproduction priority information in the header information obtained in the content data analyzing section.~~

[0205] In addition, in one embodiment of the data processing apparatus of the present invention, the data processing apparatus ~~is characterized by further comprising~~ includes retrieving means for retrieving ~~an~~ the specific expansion processing program, and ~~characterized in that the~~ retrieving means has a configuration for retrieving an expansion processing program applicable to a type of the compression processing program of the compressed contents analyzed by the content data analyzing section with program storing means accessible by the data processing apparatus as an object of retrieval.

[0206] In addition, in one embodiment of the data processing apparatus of the present invention, the data processing apparatus ~~is characterized by further comprising~~ includes displaying means for displaying information of the compressed contents ~~that are objects of expansion processing,~~ and inputting means for inputting reproduction contents identification data selected from the ~~content information displayed on the displaying means, and~~ ~~characterized in that~~ wherein the expansion processing section has a configuration for executing the expansion processing of the compressed contents corresponding to the identification data based on the reproduction contents identification data ~~inputted from the inputting means.~~

[0207] In addition, a thirty seventh aspect of the present invention is a data processing method for ~~performing~~ reproduction processing of reproducing content data. The

content data includes compressed contents and an expansion processing program of the compressed contents. The content data is provided by a storage medium or a communication medium, which is characterized by. The method comprising: a content data analyzing step of executing content data analysis of the content data including compressed contents and an expansion processing program of the compressed contents, and; executing extraction extracting processing of the compressed contents and the expansion processing program from the content data; and an expansion processing step of executing expansion processing of the compressed content data included in the content data using an the expansion processing program included in the content data obtained as a result of the analysis of the content data analyzing section.

[0208] In addition, in one embodiment of the data processing method of the present invention, the data processing method is characterized by further comprising: a data storing step of storing the extracted compressed contents that are extracted by the content data analyzing section; and a program storing step of storing the extracted expansion processing program extracted by the content data analyzing section, and characterized in that wherein the expansion processing section has a configuration for executing expansion processing is executed with respect to the compressed contents stored in the data storing step by applying the expansion processing program stored in the program storing step to the compressed contents.

[0209] In addition, in one embodiment of the data processing method of the present invention, the data processing method is characterized in that the contents data analyzing step further includes obtains obtaining a configuration information of the content data based on header information included in the content data and performs analysis of the content data prior to executing the content data analysis.

[0210] In addition, in one embodiment of the data processing method of the present invention, the data processing method is characterized in that reproduction

~~priority information of the compressed contents is~~ includes reproduction priority information included in the header information and, if If there are a plurality of compressed contents ~~that is objects of expansion processing in the expansion processing section,~~ the expansion processing step sequentially executes content expansion processing in accordance with the ~~priority based on the~~ reproduction priority information in the header information obtained in the content data analyzing step.

[0211] In addition, in one embodiment of the data processing method of the present invention, the data processing method ~~is characterized by further comprising:~~ includes displaying step of displaying information of the compressed contents that are objects of expansion processing on displaying means, and ~~inputting step of inputting reproduction contents identification data selected from the content display and information displayed on the displaying means, and characterized in that~~ wherein the expansion processing ~~step executes expansion processing of the compressed contents~~ is performed corresponding to the identification data based on the reproduction contents identification data ~~inputted from the inputting step.~~

[0212] In addition, a thirty eighth aspect of the present invention is a data processing method for ~~performing reproduction processing of reproducing content data.~~ The content data includes one of compressed contents and an expansion processing program. The content data is provided by a storage medium or a communication medium, which is characterized by comprising: The method includes a content data analyzing step of receiving content data including either compressed contents or expansion processing program, distinguishing whether the content data ~~has~~ includes the compressed contents or the expansion processing program from header information included in the received content data ~~and,~~ at the same time, ~~if~~ If the content data ~~has~~ includes the compressed contents, the method includes obtaining analyzing a type of a compressing processing program applied to the compressed contents from the header information of the content

~~data, and. if~~ If the content data ~~has~~ includes the expansion processing program, the method includes analyzing ~~obtaining~~ a type of ~~the~~ expansion processing program from the header information ~~of the content data,~~. The method also includes a selecting step of selecting an a specific expansion processing program applicable to the type of ~~the~~ compression processing program ~~of the compressed contents analyzed in the content data analyzing step~~ based on the type of ~~the~~ expansion processing program ~~analyzed in the content data analyzing step,~~, and an expansion processing step of executing expansion processing ~~by using the specific~~ expansion processing program selected in the selecting step.

[0213] In addition, in one embodiment of the data processing method of the present invention, the data processing method ~~is characterized by further comprising~~ includes: a data storing step of storing the compressed contents ~~that are extracted by the content data analyzing section,~~ and a program storing step of storing the specific expansion processing program ~~extracted by the content data analyzing section, and characterized in that~~ wherein the expansion processing step ~~executes expansion processing with respect to the compressed contents stored in the data storing step~~ is executed by applying the specific expansion processing program ~~stored in the program storing step to the compressed contents.~~

[0214] In addition, in one embodiment of the data processing method of the present invention, ~~the data processing method is characterized in that~~ reproduction priority information ~~of the~~ is associated with the compressed contents. The reproduction priority information is included in the header information ~~and,~~. ~~if~~ If there are a plurality of compressed contents ~~that is objects of expansion processing,~~ the ~~content~~ expansion processing step includes sequentially ~~executes~~ executing the ~~content~~ expansion processing in accordance with the ~~priority based on the~~ reproduction priority information ~~in the header information obtained in the content data analyzing step.~~

[0215] In addition, in one embodiment of the data processing method of the present invention, the data processing method is ~~characterized by comprising~~further includes a retrieving step of retrieving an the specific expansion processing program, and characterized in that the retrieving step retrieves an expansion processing program applicable to a type of the compression processing program of the compressed contents analyzed in the content data analyzing step with from a program storing means accessible by the data processing apparatus as an object of retrieval.

[0216] In addition, in one embodiment of the data processing method of the present invention, the data processing method is ~~characterized by~~ further comprising~~includes~~ a displaying step of displaying information of the compressed contents that are objects of expansion processing; and an inputting step of inputting reproduction contents identification data selected from the content information displayed information, on the displaying means, and characterized in thatwherein the expansion processing step executes expansion processing of is performed on the compressed contents corresponding to the identification data based on the reproduction contents identification data inputted from the inputting means.

[0217] In addition, a thirty ninth aspect of the present invention is a content data generating method for ~~performing generation processing of~~generating content data. The content data is provided by a storage medium or a communication medium, which is characterized by. The method comprises combining compressed contents and an expansion processing program, and generating the content data in whichincluding the compressed contents and an the expansion processing program of the compressed contents are combined.

[0218] In addition, in one embodiment of the content data generating method of the present invention, the content data generating method is ~~characterized in that~~ a further includes adding configuration information of the content data is added as header information of the content data.

[0219] In addition, in one embodiment of the content data generating method of the present invention, ~~the content data generating method is characterized in that~~ header information includes reproduction priority information of contents included in the content data as header information of the content data.

[0220] In addition, a fortieth aspect of the present invention is a content data generating method for ~~performing generation processing of~~ generating content data. The content data is provided by a storage medium or a communication medium. ~~The method comprises which is characterized in that content data is generated in which a type of content data for identifying whether the content data has, as header information, compressed contents or an expansion processing program is added as header information; . if~~ If the content data has the compressed contents, a type of a compression processing program is applied to the compressed contents is added as header information; and . if ~~If the content data has an the expansion processing program, a type of an expansion processing program is added as header information.~~

[0221] In addition, in one embodiment of the content data generating method of the present invention, ~~the content data generating method is characterized in that~~ further includes adding reproduction priority information of contents included in the content data as header information of the content data.

[0222] In addition, a forty first aspect of the present invention is a ~~program providing~~ recording medium for providing ~~recorded with a computer program that causes a computer system to execute reproduction processing of~~ for reproducing content data. The content data includes compressed contents and an expansion processing program for the compressed contents. The content data is provided by a storage medium or a communication medium, which is characterized by comprising: The computer program comprises a content data analyzing step of executing content data analysis of the content data including compressed contents and an expansion processing program of the compressed contents, and executing

~~extraction processing of extracting the compressed contents and the expansion processing program from the content data, and an expansion processing step of executing expansion processing of the extracted content data included in the content data using an the expansion processing program included in the content data obtained as a result of the analysis of the content data analyzing section.~~

[0223] The program providing medium in accordance with the present invention is, for example, a medium for providing a computer program in a computer readable form to a general purpose computer system that can execute various program codes. A form of the medium is a storage medium such as a CD, an FD or an MO, or a transmission medium such as a network, and is not specifically limited.

[0224] Such a program providing medium defines a structural or functional cooperative relationship between a computer program and a providing medium for realizing a predetermined function of the computer program on a computer system. In other words, a cooperative operation is shown on the computer system by installing the computer program in the computer system via the providing medium, and operational effects similar to other aspects of the present invention can be obtained.

[0225] Other objects, features, and advantages of the present invention will be seen from the detailed explanation based on the embodiment and attached drawings of the present invention described later.

[0226] As described above, according to the data processing apparatus and method and data-verifying-value-imparting method of the present invention, partial integrity check values generated as integrity check values for a partial data set containing one or more partial data obtained by dividing content data into a plurality of pieces are used for a collation process to verify the partial data, and a partial-integrity-check-value -verifying integrity check values used to verify a partial integrity check value set comprising a combination of a plurality of partial integrity check values are used for a collation process to verify the entirety of a

plurality of partial data sets corresponding to a plurality of partial integrity check values constituting a partial integrity check value set. Consequently, compared to a configuration for imparting a single integrity check value to the entire content data, partial verification is achieved and the entire verification process is efficient due to the use of the partial integrity check values.

[0227] Further, according to the data processing apparatus and method and data-verifying-value-imparting method of the present invention, the verification process can be executed depending on how content data are used, for example, whether the data are to be downloaded or reproduced; for example, a verification process for a data portion that is unlikely to be tampered can be omitted. Therefore, efficient verification is achieved depending on how data are used.

[0228] Furthermore, the data processing apparatus and data processing method of the present invention are configured in such a way that individual keys necessary to execute encryption processing such as data encryption, data decryption, data verification, authentication processing and signature processing are not stored in a storage section, master keys to generate these individual keys are stored in the storage section instead, the encryption processing section of the data processing apparatus extracts the master keys corresponding to these individual keys such as encryption keys and authentication keys from the storage section as required, executes encryption processing applying a DES algorithm, etc. based on the extracted master keys and identification data of the apparatus or data and generates individual keys such as an encryption key and authentication key, and therefore the present invention eliminates the possibility of the individual keys themselves leaking from the storage section and enhances the security of an encryption processing system because acquiring the individual keys will require a plurality of information pieces such as information of both individual key generation algorithm and master keys, identification data of the apparatus or data. Moreover, even if an individual key is leaked for some reasons, the range of damage is limited to the

range of the individual key, which will not lead to collapse of the entire system.

[0229] Furthermore, the data processing apparatus, data processing system and data processing method of the present invention is configured in such a way that individual keys are sequentially generated based on the identification data of the apparatus or data, which eliminates the need to maintain the list of keys applied to individual apparatuses in a control apparatus, facilitating system control as well as enhancing the security.

[0230] Furthermore, according to the data processing apparatus, data processing method and contents data generation method of the present invention, illegal device identification data information is stored in contents data, collation between an illegal device list and the recorder/reproducer identifier of the recorder/reproducer attempting to use the contents is executed prior to the use of the contents by the recorder/reproducer, and in the case where the collation result shows that some entries of the illegal device list match the recorder/reproducer identifier, the subsequent processing, for example, contents data decryption, downloading or reproduction processing, etc. is stopped, thus making it possible to prevent a reproducer, etc. that has illegally acquired a key from illegally using contents.

[0231] Furthermore, the data processing apparatus, data processing method and contents data generation method of the present invention adopt a configuration allowing the contents data to include check values together for the illegal device list in the content data, making it possible to prevent tampering of the list itself and provide a contents data utilization configuration with enhanced security.

[0232] Furthermore, the data processing apparatus and data processing method of the present invention allows a data processing apparatus such as a recorder/reproducer and PC to store an apparatus-specific key, which is specific to the data processing apparatus and a system common key, which is common to other data processing apparatuses using contents data, making it possible to process contents according to contents

utilization restrictions. The data processing apparatus selectively uses these two keys according to contents utilization restrictions. For example, in the case where the contents are only available to the data processing apparatus, the key specific to the data processing apparatus is used, while in the case where the contents are also available to other systems, a check value for the contents data is generated and collation processing is performed using the system common key. It is possible to decrypt and reproduce the encrypted data only when the collation is established, thus allowing processing according to contents utilization restrictions such as contents only available to the data processing apparatus or contents commonly available to the system, etc.

[0233] Furthermore, the data processing apparatus, data processing method and contents data verification value assignment method of the present invention is configured to generate a contents check value in units of contents block data, execute collation processing on the contents check value generated, generate a contents intermediate value based on the contents block data to be verified and generate a contents check value through encryption processing applying a contents check value generation key, thus allowing efficient verification compared to conventional processing on entire data.

[0234] Furthermore, the data processing apparatus, data processing method and contents data verification value assignment method of the present invention allows verification in contents block units and simplified verification processing according to download processing and reproduction processing, etc. providing efficient verification according to the mode of use.

[0235] Furthermore, since the data processing apparatus, the content data generating method, and the data processing method of the present invention is made to have the configuration that is provided with the plurality of content blocks in the content data and enables encryption processing for a unit of each content block, and also have the

configuration in which the key used for content encryption is further encrypted and stored in the header section, even if, for example, a plurality of content blocks exist and blocks requiring encryption processing and blocks not requiring encryption processing are mixed, it becomes possible to have an arbitrary data structure that couples each block.

[0236] In addition, according to the data processing apparatus, the data processing system, and the data processing method of the present invention, by making the configuration of the content block to be a regular configuration, for example, a configuration having a uniform data length, or a configuration in which the encryption block and the non-encryption (plaintext) block are alternately disposed, decryption processing and the like of the content block can be promptly executed, and encryption content data suitable for processing corresponding to contents of the content data, for example, reproduction and the like of music data can be provided.

[0237] Furthermore, the data processing apparatus, the data processing method and the content data generating method can efficiently execute reproduction processing in the case in which contents are compressed voice data, image data or the like. That is, by making a configuration of content data to be one in which compressed data and an expansion processing program are combined, expansion processing, to which an expansion processing program incidental to compressed content data is applied, is made possible in the reproduction processing apparatus, and a situation in which the expansion processing program does not exist in the reproduction processing apparatus and reproduction cannot be performed can be avoided.

[0238] Moreover, according to the data processing apparatus, the data processing method and the content data generating means, since a configuration of content data has a configuration in which the reproduction processing apparatus determines the expansion processing program applicable to the compressed content data based on the header information, and the reproduction processing apparatus further retrieves a

program applicable from accessible recording media or the like and executes expansion processing by making content data to be a combination of compressed data and the header section storing the type of the compression processing program, or, if the contents has the expansion processing program, a combination of the expansion processing program and the header storing the type of the program, program retrieving processing does not need to be executed by a user, and efficient reproduction processing becomes possible.

BRIEF DESCRIPTION OF THE DRAWINGS~~Brief Description of the Drawings~~

[0239] Fig. 1 is a view showing the configuration of a conventional data processing system.

[0240] Fig. 2 is a view showing the configuration of a data processing apparatus to which the present invention is applied.

[0241] Fig. 3 is a view showing the configuration of a data processing apparatus to which the present invention is applied.

~~Best Mode for Carrying out the Invention~~ DETAILED DESCRIPTION

[0332] The embodiments of the present invention will be described below. The description will proceed in the order of the following items:

- (1) Configuration of Data Processing apparatus
- (2) Content Data Format
- (3) Outline of Cryptography Processes Applicable to Present Data Processing Apparatus
- (4) Configuration of Data Stored in Recording and Reproducing Apparatus
- (5) Configuration of Data Stored in Recording Device
- (6) Mutual Authentication Process between Recording and Reproducing Device and Recording Device
 - (6-1) Outline of Mutual Authentication Process
 - (6-2) Switching to Key Block during Mutual Authentication
- (7) Process for Downloading from Recording and Reproducing Device to Recording Device
- (8) Process Executed by Recording and Reproducing Device to Reproduce Information from Recording Device
- (9) Key Exchanging Process after Mutual Authentication
- (10) Plural Content Data Formats and Download and Reproduction Processes Corresponding to Each Format
- (11) Aspect of Process Executed by Content Provider to Generate Check Values (ICV)
- (12) Cryptography Process Key Generating Configuration Based on Master Key
- (13) Controlling Cryptography Intensity in Cryptography Process
- (14) Program Activating Process Based on Activation Priority in Handling Policy in Content Data

(15) Content Configuration and Reproduction (Decompression) Process

(16) Process for Generating and storing Saved Data in Recording Device and Reproducing the Same therefrom

(17) Configuration for Excluding (Revoking) Illegal Apparatuses

(18) Secure Chip Configuration and Manufacturing Method therefor

(1) Configuration of Data Processing Apparatus

[0333] Fig. 2 ~~illustrates~~shows a block diagram showing the general configuration of one embodiment of a data processing apparatus according to the present invention. Main components of the data processing apparatus are a recording and reproducing device 300 and a recording device 400.

[0334] The recording and reproducing device 300 comprises, for example, a personal computer (PC), a game apparatus, or the like. The recording and reproducing device 300 has a control section 301 for carrying out unifying control including the control of communication between the recording and reproducing device 300 and the recording device 400 during a cryptography process in the recording and reproducing device 300.7 The recording and reproducing device 300 also includes a recording and reproducing device cryptography process section 302, which is responsible for the whole cryptography process. It also includes a recording device controller 303 for executing an authentication process with the recording device 400 connected to the recording and reproducing device 300 to read and write data.7 Recording and reproducing device 300 further includes a read section 304 for at least reading data from a medium 500, such as a DVD, CD, floppy disk (FD) or hard disk (HDD), and a communication section 305 for transmitting and receiving data to and from the exterior network, via communication means 600~~as shown in Fig. 2.~~

[0335] The recording and reproducing device 300 downloads and reproduces content data to and from the recording device 400 controlled by the control section 301. The recording device 400 is a storage medium that can preferably be installed in and removed from the recording and reproducing

device 300, for example, as a memory card. The recording device 400~~and~~ has an external memory 402 comprising a non-volatile memory such as an EEPROM, ~~or a flash memory, a hard disk, or a RAM with batteries.~~

[0336] The recording and reproducing device 300 has ~~at the~~ read section 304 as an interface to which content data stored in the storage medium 500~~shown at the left end of Fig. 2, that is, a DVD, a CD, an FD, or an HDD can be input,~~ and ~~a~~ The communication section 305 acts as an interface to which content data distributed from an exterior network such as the Internet can be input, ~~in order to receive an input of a content from the exterior.~~

[0337] The recording and reproducing device 300 has ~~at the~~ cryptography process section 302 to execute an authentication process, an encryption and a decryption processes, a data verification process, ~~and/or~~ other processes. The cryptography process section 302 operates in downloading content data externally input via the read section 304 or the communication section 305, to the recording device 400 or reproducing and executing content data from the recording device 400. The cryptography process section 302 comprises a control section 306, an internal memory 307 and an encryption/decryption section 308. ~~Control Section 306 for controlling controls the entire cryptography process section 302.~~ ~~an~~ The internal memory 307 holds information such as keys for the cryptography process and which has been processed so as to prevent data from being externally read out therefrom easily, ~~and an encryption/decryption section 308~~ Encryption/decryption section 308 is used for executing the encryption and decryption processes, generating and verifying authentication data, generating random numbers, etc.

[0338] The control section 301 transmits an initialization command to the recording device 400 via the recording device controller 303 when, for example, the recording device 400 is installed in the recording and reproducing device 300. ~~or~~ Control section 301 can also execute a mediation process for various processes such as a mutual authentication between the encryption/decryption section 308 ~~of the recording and~~

~~reproducing device cryptography process section 302 and the encryption/decryption section 406 of the recording device cryptography process section 401.~~ Control section 301 can also perform an integrity check value collating process, and encryption and decryption processes. Each of these processes will be described in detail ~~later in the latter part.~~

[0339] The cryptography process section 302 can executes the authentication process, the encryption and decryption processes, the data verifying process, and other processes, as previously described, ~~and has the cryptography process control section 306, the internal memory 307, and the encryption/decryption section 308.~~

[0340] The cryptography process control section 306 executes control of the whole cryptography process. ~~such as~~ This includes the authentication process and the encryption/decryption processes executed by the recording and reproducing device 300. These are, for example, processes of setting an authentication completion flag when the authentication process executed between the recording and reproducing device 300 and the recording device 400 has completed, and commanding the execution of various processes executed in the encryption/decryption section 308 ~~of the recording and reproducing section cryptography process section 302.~~ Some of the various processes are, for example, a download process, and a process for generating integrity check values for reproduced content data, and commanding the execution of a process for generating various key data.

[0341] The internal memory 307 stores key data, identification data, and other data required for various processes. ~~such as~~ Some of the various processes include the mutual authentication process, the integrity check value collating process, and the encryption and decryption processes which are executed in the recording and reproducing device 300. as These processes will be described later in detail.

[0342] The encryption/decryption section 308 uses key data and ~~the like~~ similar information stored in the internal memory 307 to execute the authentication process, the encryption and decryption processes, the generation and verification of

predetermined integrity check values or electronic signatures, the verification of data, the generation of random numbers, etc. in downloading externally input content data to the recording device 400 or reproducing and executing content data stored in the recording device 400.

[0343] In this case, the internal memory 307 of the recording and reproducing device cryptography process section 302 holds important information such as cryptography keys and ~~must thus be~~ configured so as not to have its data externally read out easily. Thus, the cryptography process section 306 is configured as a tamper-resistant memory characterized to restrain external invalid reads. ~~in that it~~ It comprises, for example, a semiconductor chip that essentially rejects external accesses and has a multilayer structure, an internal memory sandwiched between dummy layers of aluminum or the like or arranged in the lowest layer, and a narrow range of operating voltages and/or frequencies. This configuration will be described later in detail.

[0344] In addition to these cryptography process functions, the recording and reproducing device 300 comprises a main Central Processing Unit (CPU) 106, a RAM (Random Access Memory) 107, a ROM (Read Only Memory) 108, an AV process section 109, an input interface (I/F) 110, a PIO (Parallel I/O) interface 111, and a SIO (Serial I/O) interface 112.

[0345] ~~The main Central Processing Unit (CPU) 106, the RAM (Random Access Memory) 107, and the ROM (Read Only Memory) 108~~ are a components functioning as a control system for the main body of the recording and reproducing device 300. CPU 106, RAM 107 and ROM 103 ~~and~~ principally functions as a reproduction process section for reproducing data decrypted by the ~~recording and reproducing device cryptography process section 302.~~ For example, the main ~~Central Processing Unit (CPU)~~ 106 executes control for the reproduction and execution of contents, such as output of content data read out from the recording device and then decrypted, to the AV process section 109 under the control of the control section 301.

[0346] The RAM 107 is used as a main storage memory for various processes executed by the CPU 106 and as a working

area for these processes. The ROM 108 stores a basic program for starting up an Operating System (OS) or the like activated by the CPU 106, ~~and~~ as well as other data.

[0347] The AV process section 109 has a data compression and decompression process mechanism. Specifically, the AV process section 109 includes an MPEG2 decoder, an ATRAC decoder, an MP3 decoder, etc., or the like, to execute processes for data outputs to a data output apparatus such as a display or speakers (not shown) attached or connected to the recording and reproducing device 300 main body.

[0348] The input I/F interface 110 outputs ~~input data~~ input from various connected input means such as a controller, a keyboard, and a mouse, to the main CPU 106. The main CPU 106 executes a process in accordance with a command issued by a user via the controller, based on, for example, a game program being executed ~~or the like~~.

[0349] The ~~PIO (Parallel I/O)~~ interface 111 and the ~~SIO (Serial I/O)~~ interface 112 are used as storage devices for a memory card or a game cartridge and as a connection interface to a portable electronic device or the like.

[0350] The main CPU 106 also executes control in storing ~~as~~ saved data, setting data or the like for, as an example, a game being executed ~~or the like~~. During this process, stored data ~~are~~ is transferred to the control section 301, ~~which~~ This causes the cryptography process section 302 to execute a cryptography process for the saved data as required and then stores the encrypted data in the recording device 400. These cryptography processes will be described later in detail.

[0351] The recording device 400 is a storage medium that can preferably be installed in and removed from the recording and reproducing device 300, and comprises, for example, a memory card. The recording device 400 has the cryptography process section 401 and the external memory 402.

[0352] The recording device cryptography process section 401 executes the mutual authentication process, encryption and decryption processes, data verification process, and other processes. These processes occur between the recording and reproducing device 300 and the recording device 400 in

downloading content data from the recording and reproducing device 300 or reproducing content data from the recording device 400 to the recording and reproducing device 300, ~~and~~ The cryptography process section 401 has a control section, an internal memory, an encryption/decryption section, and others components similarly to the cryptography process section of the recording and reproducing device 300. The details will be ~~shown~~ indescribed in relation to Fig. 3. The external memory 402 stores encrypted content data or the like. It comprises a non-volatile memory comprising a flash memory such as an EEPROM, a hard disk, ~~or a RAM with batteries,~~ or the like, ~~to store encrypted content data or the like.~~

[0353] Fig. 3 is a view schematically showing the configuration of data input from athe medium 500 and athe communication means 600 that are datacontent providing means from which the data processing apparatus according to the present invention receives data, ~~and focusing on the configurations of~~ tThe recording and reproducing device 300 receives ing an input of a content from the content providing means 500 or 600. ~~and of~~ Recording and reproducing device 300 operates on arrangements for the cryptography process in the recording device 400.

[0354] The medium 500 is, for example, an optical disk medium, a magnetic disk medium, a magnetic tape medium, a semiconductor medium, or the like. The communication means 600 is capable of data communication ~~such as~~ via the Internet, cable, or satellite communication.

[0355] In Fig. 3, the recording and reproducing device 300 verifies data input by the medium 500 or the communication means 600. T, ~~that is,~~ a recording and reproducing device 300 verifies content meeting a predetermined format, ~~as shown in Fig. 3,~~ and stores the verified content in the recording device 400.

[0356] As shown in the sections of the medium 500 and communication means 600 ~~in Fig. 3,~~ the content data has the following components:

Content ID: content ID as an identifier for content data.

[0357] Usage policy: a usage policy containing constituent information of content data. For example, the usage policy contains the sizes of a header section and a content section constituting the content data, a format version, a content type indicating whether the content is a program or data, and a localization field indicating whether the content can be used only in an apparatus that has downloaded the content or also in other apparatuses.

[0358] Block information table: the block information table comprisesing the number of content blocks, a block size, an encryption flag indicating the presence of encryption, and others information.

[0359] Key data: key data comprisesing an encryption key for encrypting the above described block information table, a content key for encrypting a content block, or the like.

[0360] Content block: the content block comprisesing program data, music or image data, or other data to be actually reproduced.

[0361] The content data will be explained later in further detail with reference to Fig. 4 and subsequent figures.

[0362] The content data are encrypted by the content key (hereafter referred to as the "Knon") and then provided to the recording and reproducing device 300 from the medium 500 or the communication means 600. The content can be stored in the external memory of the recording device 400 via the recording and reproducing device 300.

[0363] For example, the recording device 400 uses a key (hereafter referred to as a "storage key", or {Kstr}) unique thereto. The storage key is stored in the internal memory 405 thereof to encrypt the content contained in the content data, the block information table contained in the content data as header information, and information on various keys, such as the content key Kcon. This is done before storing these data in the external memory 402. To download the content data from the recording and reproducing device 300 to the recording device 400 or allow the recording and reproducing device 300 to reproduce the content data stored in the recording device 400, predetermined procedures such as a mutual authentication

process between the apparatuses and content data encrypting and decrypting processes are required. These processes will be explained later in detail.

[0364] The recording device 400 has the cryptography process section 401 and the external memory 402. ~~and~~ ~~the~~ The cryptography process section 401 has a control section 403, a communication section 404, the internal memory 405, an encryption/decryption section 406, and an external memory control section 407.

[0365] The recording device 400 is responsible for the whole cryptography process, controls the external memory 402, and comprises the recording device cryptography process section 401. cryptography process section 401 is for interpreting a command from the recording and reproducing device 300 and executing a process. ~~and~~ The recording device 400 also includes the external memory 402, which holds ~~ing~~ contents or the like.

[0366] The recording device cryptography process section 401 has the control section 403 for controlling the entire recording device cryptography process section 401, the communication section 404 for transmitting and receiving data to and from the recording and reproducing device 300, ~~and~~ the internal memory 405. Internal memory 405 holds ~~ing~~ information such as keys for the cryptography process. ~~and which~~ The information has been processed so as to prevent data from being easily externally read out therefrom ~~easily.~~ ~~and~~ ~~the~~ The encryption/decryption section 406 is used for executing the encryption and decryption processes, generating and verifying authentication data, generating random numbers, etc. ~~and~~ ~~the~~ The external memory control section 407 is used for reading and writing data from and to the external memory 402.

[0367] The control section 403 executes control of the whole cryptography process. ~~such as~~ This includes the authentication process and the encryption/decryption processes executed by the recording device 400. ~~and~~ The encryption/decryption processes include, for example, processes of setting an authentication completion flag when the authentication process executed between the recording and

reproducing device 300 and the recording device 400 has completed. ~~The control section 403 also commands~~ the execution of various processes executed in the encryption/decryption section 406 of the cryptography process section 401. ~~For example, the various processes can include a download process and a process for generating integrity check values for reproduced content data.~~ ~~The control section 403 also commands~~ the execution of a process for generating various key data.

[0368] The internal memory 405 comprises a memory having a plurality of blocks to store a plurality of sets of key data, identification data, or other data which are required for various processes. ~~Such various processes include as~~ the mutual authentication process, integrity check value collating process, and ~~an~~ encryption and decryption process, which are executed by the recording device 400, as described later in detail.

[0369] The internal memory 405 of the recording device cryptography process section 401, like the internal memory 307 of the ~~recording and reproducing device~~ cryptography process section 302 previously described, holds important information such as cryptography keys. Internal memory 307 ~~and must thus~~ be configured so as not to have its data externally read out easily. Thus, the cryptography process section 401 of the ~~recording and reproducing~~ device 400 is characterized to restrain external invalid reads. ~~in that i~~ It comprises a semiconductor chip that essentially rejects external accesses and has a multilayer structure, an internal memory sandwiched between dummy layers of aluminum or the like or arranged in the lowest layer, and a narrow range of operating voltages and/or frequencies. In this regard, the ~~recording and reproducing device~~ cryptography process section 302 may be software configured so as to prevent secret information for keys from leaking easily to the exterior network or the like.

[0370] The encryption/decryption section 406 uses key data or the like stored in the internal memory 405 to execute the data verifying process, the encryption and decryption processes, the generation and verification of predetermined

integrity check values or electronic signatures, the generation of random numbers, etc. It does this in downloading content data from the recording and reproducing device 300, reproducing content data stored in the external memory 402 of the recording device 400, or executing mutual authentication between the recording and reproducing device 300 and the recording device 400.

[0371] The communication section 404 is connected to the recording device controller 303 of the recording and reproducing device 300. ~~to~~ The communication section 404 downloads or reproduces content data or communicates transfer data between the recording and reproducing device 300 and the recording device 400 during the mutual authentication process. This is done according to the control of the control section 301 of the recording and reproducing device 300, or the control of the control section 403 of the recording device 400.

(2) Content Data Format

[0372] Next, by using Fig. 4 to Fig. 6, the data format of data stored in the medium 500 ~~of the system according to the present invention~~ or communicated on the data communication means 600 will be explained.

[0373] The configuration shown in Fig. 4 shows the format of the entire content data. ~~to~~ The configuration shown in Fig. 5 shows details of the "usage policy" that partly constitutes the header section of the content data. ~~and~~ The configuration shown in Fig. 6 shows details of the "block information table" that partly constitutes the header section of the content.

[0374] A representative example of the data format applied to the system according to the present invention will be explained. ~~but~~ However, different types of data formats, such as formats corresponding to game programs and formats suitable for real-time processing of music data or the like, can be used for the present system. The aspects of these formats will be described later in further detail, in "(10) Plural Content Data Formats and Download and Reproduction Processes Corresponding to Each Format."

[0375] In the data format shown in Fig. 4, items shown in gray indicate encrypted data.~~;~~~~i~~ Items enclosed by double frames indicate tamper check data.~~;~~~~and~~~~t~~ The other items shown in white indicate plain text data that are not encrypted. Encryption keys of the encryption section are shown on the left of the frames. In the example shown in Fig. 4, some of the blocks (content block data) of the content section contain encrypted data, while the others contain non-encrypted data. This form varies depending on the content data.~~;~~~~and~~~~a~~ All the content block data contained in the data may be encrypted.

[0376] As shown in Fig. 4, the data format is divided into the header section and the content section.~~;~~~~and~~~~t~~ The header section comprises a content ID, a usage policy, an integrity check value A (hereafter referred to as "ICVa"), a block information table key (hereafter referred to as "Kbit"), a content key Kcon, a block information table (hereafter referred to as "BIT"), an integrity check value B ("ICVb"), and a total integrity check value ("ICVt").~~;~~~~and~~~~t~~ The content section comprises a plurality of content blocks, ~~{for example, encrypted and non-encrypted contents}~~.

[0377] In this case, the individual information indicates a content ID for identifying a specific piece of content. The usage policy, as shown in Fig. 5, comprises a header length indicating the size of the header section;~~;~~ a content length indicating the size of the content section;~~;~~ a format version indicating version information for the format;~~;~~ a format type indicating the type of the format;~~;~~ a content type indicating the type of the content, that is, whether it is a program or data;~~;~~ an operation priority indicating a priority for activation if the content type is a program;~~;~~ a localization field indicating whether the content downloaded in accordance with this format can be used only in an apparatus that has downloaded the content or also in other similar apparatuses;~~;~~ a copy permission indicating whether the content downloaded in accordance with this format can be copied from the apparatus that has downloaded the content to another similar apparatus;~~;~~ a move permission indicating whether the content downloaded in accordance with this format can be moved from the apparatus

that has downloaded the content to another similar apparatus; an encryption algorithm indicating an algorithm used to encrypt content blocks in the content section; an encryption mode indicating a method for operating the algorithm used to encrypt the content in the content section; and an integrity check method indicating a method for generating integrity check values, as shown in detail in Fig. 5.

[0378] The above described data items recorded in the usage policy are only exemplary and various usage policy information can be recorded depending on the aspect of corresponding content data. The identifier as is described later in detail in, for example, "(17) Configuration for Excluding (Revoking) Illegal Apparatuses." It is also possible to make a configuration so as to exclude the use of content caused by the illegal apparatus by recording the content of an illegal recording and reproducing apparatus as data and by checking the start time of ~~starting~~ the use.

[0379] The integrity check value A ICVa is used to verify that the content ID or the usage policy has not been tampered with. It functions as a check value for partial data instead of the entire content data. ~~That is,~~ it functions as a partial integrity check value. The data block information table key Kbit is used to encrypt a block information table. ~~and~~ The content key Kcon is used to encrypt content blocks. The block information table key Kbit and the content key Kcon are encrypted with a distribution key (hereafter referred to as "Kdis") on the medium 500 and the communication means 600.

[0380] Fig. 6 shows the block information table in detail. The block information table in Fig. 6 comprises data all encrypted with the block information table key Kbit as seen illustrated in Fig. 4. The block information table comprises a block number, indicating the number of content blocks and information on N content blocks, ~~as shown in Fig. 6.~~ The content block information table comprises a block length; an encryption flag indicating whether or not the block has been encrypted; an ICV flag indicating whether or not integrity check values must be calculated, and a content integrity check value (ICVi).

[0381] The content integrity check value is used to verify that each content block has not been tampered with. A specific example of a method for generating a content integrity check value will be explained later in "(10) Plural Content Data Formats and Download and Reproduction Processes Corresponding to Each Format." The block information table key Kbit, used to encrypt the block information table, is further encrypted with the distribution key Kdis.

[0382] The data format in Fig. 4 will be ~~continuously~~ described further. The integrity check value B, ICVb, is used to verify that the block information table key Kbit, the content key Kcon, and the block information table have not been tampered with. It functions as a check value for partial data instead of the entire content data, ~~that is, it~~ functions as a partial integrity check value. The total integrity check value ICVt is used to verify the integrity check values ICVa and ICVb, integrity check values ICVi for each content block (if this has been set), partial integrity check values thereof, or all the data to be checked have not been tampered with.

[0383] In Fig. 6, the block length, the encryption flag, and the ICV flag can be arbitrarily set, ~~but~~ However, certain rules may be established. For example, encrypted- and plain-text areas may be repeated over a fixed length, all the content data may be encrypted, or the block information table BIT may be compressed. Additionally, the content key Kcon may be contained in the content block instead of the header section to allow different content keys Kcon to be used for different content blocks, ~~the content key Kcon may be contained in the content block instead of the header section.~~ Examples of the content data format will be described in further detail in "(10) Plural Content Data Formats and Download and Reproduction Processes Corresponding to Each Format."

(3) Outline of Cryptography Processes Applicable to Present Data Processing Apparatus

[0384] Next, the aspects of various cryptography processes applicable to the data processing apparatus according to the present invention will be explained. The description of the cryptography processes shown in "(3) Outline of Cryptography Processes Applicable to Present Data Processing Apparatus" correspond to an outline of the aspect of a cryptography process on which are based various processes executed by the present data processing apparatus, which will be specifically described later. ~~f~~For example, "a. authentication process between recording and reproducing device and recording device", "b. download process for device for loading contents", and "c. process for reproducing content stored in recording device" will be explained herein. Specific processes executed by the recording and reproducing device 300 and the recording device 400 will be each described in detail in ~~the~~ item (4) and subsequent items.

[0385] An outline of the cryptography process applicable to the data processing apparatus will be described in the following order:

- (3-1) Message Authentication Based on Common Key Cryptosystem
- (3-2) Electronic Signature Based on Public Key Cryptosystem
- (3-3) Verification of Electronic Signature Based on Public Key Cryptosystem
- (3-4) Mutual Authentication Based on Common Key Cryptosystem
- (3-5) Public Key Certificate
- (3-6) Mutual Authentication Based on Public Key Cryptosystem
- (3-7) Encryption Process Using Elliptic Curve Cryptography
- (3-8) Decryption Process Using Elliptic Curve Cryptography
- (3-9) Random Number Generating Process

- (3-1) Message Authentication Based on Common Key Cryptosystem

[0386] First, a process for generating tamper detecting data using a common key cryptography method will be explained. The tamper detecting data are added to the data to be detected ~~for tamper~~ in order to check for tampering and to authenticate a creator.

[0387] For example, the tamper detecting data may be the ICVa, integrity check values A ~~the~~ and BICVb, and the total

integrity check value in the data structure described in Fig. 4 ~~which are enclosed by double frames, and~~ the content check value stored in each block in the block information table shown in Fig. 6, ~~and the like are generated as the tamper detecting data.~~

[0388] Here, the use of the DES, which is a common key cryptosystem, will be explained as an example of a method for generating and processing electronic signature data. In addition to the DES, the present invention may use, for example, the FEAL (Fast Encipherment Algorithm or the AES (Advance Encryption Standard) (U.S. next-term standard cryptography) as a similar process based on a common key cryptosystem.

[0389] A method for generating an electronic signature using a general DES will be explained with reference to Fig. 7. First, before generating an electronic signature, a message to which the electronic signature is to be added is divided into sets of 8 bytes (the pieces of the divided message are hereafter referred to as "M1, M2, ... , MN"). An initial value (hereafter referred to as "IV") and the M1 are exclusive-ORed. ~~ORed.~~ ~~ORed.~~ The result is referred to as "I1". Next, the I1 is input to a DES encrypting section, which encrypts it using a key (hereafter referred to as "K1") ~~ORed.~~ The output is referred to as "E1". Subsequently, the E1 and the M2 are exclusive-ORed, and the output I2 is input to the DES encrypting section, which encrypts it using the key K1 ~~ORed.~~ the output is referred to as "E2". This process is repeated to encrypt all the messages (M1, M2, ... MN) obtained by means of the division. The final output ~~EN~~ is an electronic signature ("EN"). This value is generally called a "MAC (Message Authentication Code)" used to check a message for tampering. In addition, such a system for chaining encrypted texts is called a "CBC (Cipher Block Chaining) mode."

[0390] The MAC value output in the example of generation shown in Fig. 7 can be used as the integrity check value A or B or total integrity check value in the data structure shown in Fig. 4 which is enclosed by double frames and the content check value ICV1 to ICVN stored in each block in the block

information table shown in Fig. 6. In verifying the MAC value, a verifier generates it using a method similar to that used to originally generate it, ~~and t~~ The verification is determined to be successful if the same value is obtained.

[0391] Moreover, in the example shown in Fig. 7, the initial value IV is exclusive-ORed with the first 8-byte message M1, but the initial value IV may be zero and not exclusive-ORed.

[0392] Fig. 8 shows the configuration of a method for generating the MAC value which has improved security compared to the MAC value generating method shown in Fig. 7. Fig. 8 shows an example where instead of the Single DES in Fig. 7, the Triple DES is used to generate the MAC value.

[0393] Figs. 9A and 9B show an example of a detailed configuration of each of the Triple DES components shown in Fig. 8. There are two different aspects of the configuration of the Triple DES as shown in Fig. 9. Fig. 9(a) shows an example using two cryptography keys, ~~where p~~ Processing is carried out in the order of an encryption process with a key 1 (K1), a decryption process with a key 2 (K2), and an encryption process with the key 1. The two types of keys are used in the order of K1, K2, and K1. Fig. 9(b) shows an example using three cryptography keys, ~~where p~~ Processing is carried out in the order of an encryption process with the key 1, an encryption process with the key 2, and an encryption process with a key 3 (K3). The three types of keys are used in the order of K1, K2, and K3. The plurality of processes are thus continuously executed to improve security intensity compared to the Single DES. The Triple DES configuration, however, has the disadvantage of requiring an amount of processing time three times as large as that for the Single DES.

[0394] Fig. 10 shows an example of a MAC value generating configuration obtained by improving the Triple DES configuration described in Figs. 8 and 9. In Fig. 10, the encryption process for each of the messages (M1, M2,...,MN) from beginning to end of a message string to which a signature is to be added is based on the Single DES, ~~while e~~ Only the

encryption process for the last message is based on the Triple DES configuration shown in Fig. 9(a).

[0395] The configuration shown in Fig. 10 reduces the time required to generate the MAC value for the message down to a value almost equal to the time required for the MAC value generating process based on the Single DES. This is done with improved security ~~improved~~ compared to the MAC value based on the Single DES. Moreover, the Triple DES configuration for the last message may be as shown in Fig. 9(b).

(3-2) Electronic Signature Based on Public Key Cryptosystem

[0396] The method for generating electronic signature data (if the common key encryption system) is used as the encryption system has been described. ~~but a~~ A method for generating electronic signature data if a common key cryptosystem is used as the encryption system will be described with reference to Fig. 11 for a common key cryptosystem being used as the encryption system. The process shown in Fig. 11 corresponds to a process flow of generation of electronic signature data using the Elliptic Curve Digital Signature Algorithm (EC-DSA), as per IEEE P1363/D3. An example using ~~the~~ Elliptic Curve Cryptography (hereafter referred as "ECC") as public key cryptography will be explained. In addition to ~~the elliptic curve cryptography~~ ECC, the data processing apparatus according to the present invention may use, for example, ~~the~~ RSA (Rivest, Shamir, Adleman; ANSI X9.31) cryptography, which is a similar public cryptosystem.

[0397] Each step in Fig. 11 will be described. At step S1, the following definitions are set: reference symbol p denotes a characteristic. Reference symbols a and b denote coefficients of an elliptic curve (elliptic curve: $y^2 = x^3 + ax + b$). M denotes a message. G denotes a base point on the elliptic curve. Symbol r denotes the digit of ~~the~~ G . ~~and~~ K_s denotes a secret key ($0 < K_s < r$). At step S2, a hash value for the message M is calculated to obtain $f = \text{Hash}(M)$.

[0398] Then, a method for determining a hash value using a hash function will be explained. The hash function receives a message as an input, compresses it into data of a

predetermined bit length, and outputs the compressed data as a hash value. The hash value is characterized in that it is difficult to predict an input from a hash value (output). ~~in that~~ For instance, when one bit of data input to the hash function changes, many bits of the hash value change. ~~and in that~~ Thus, it is difficult to find different input data with the same hash value. The hash function employed may be, for example, MD4, MD5, ~~or~~ SHA-1, or DES-CBC similar to that described in Fig. 7 or other figures. In this case, the MAC (corresponding to the integrity check value ICV), which is the final output value, is the hash value.

[0399] Subsequently, at step S3, a random number u ($0 < u < r$) is generated. ~~and a~~ At step S4, the base point G is multiplied by u to obtain coordinates V (X_v, Y_v). An addition and a multiplication by two on the elliptic curve are defined as follows:

If $P=(X_a, Y_a), Q=(X_b, Y_b), R=(X_c, Y_c)=P+Q$.

When $P \neq Q$ (addition),

$$X_c = \lambda^2 - X_a - X_b$$

$$Y_c = \lambda x (X_a - X_c) - Y_a$$

$$\lambda = (Y_b - Y_a) / (X_b - X_a)$$

When $P=Q$ (multiplication by two),

$$X_c = \lambda^2 - 2X_a$$

$$Y_c = \lambda x (X_a - X_c) - Y_a$$

$$\lambda = (3(X_a)^2 + a) / (2Y_a) \quad \dots\dots (1)$$

[0400] These are used to multiply the point G by u . ~~(a~~ Although the calculation speed is low, the most easy-to-understand calculation method is shown below. $G, 2xG, 4xG, \dots$ is calculated, the u is binary-expanded, and corresponding $2^i \times G$ (value obtained by multiplying G by 2 i times) is added to bits of 1 (i denotes a bit position as counted from an LSB).

[0401] At step S5, $c = X_v \bmod r$ is calculated, and at step S6, is determined whether the result is zero. If the result is not zero, then at step S7, $d = [(f + cK_s) / u] \bmod r$ is calculated. ~~and a~~ At step S8, it is determined whether d is zero. If ~~the~~ d is not zero, then at step S9, ~~the~~ c and d are output as

electronic signature data. When r is assumed to denote ~~the~~a length of 160 bits, the electronic signature data have a length of 320 bits.

[0402] If ~~the~~c is 0 at step S6, the process returns to step S3 to regenerate a new random number. Similarly, if ~~the~~d is 0 at step S8, the process also returns to step S3 to regenerate a new random number.

(3-3) Verification of Electronic Signature Based on Public Key Key Cryptosystem

[0403] Next, a method for verifying an electronic signature using the public key cryptosystem will be described with reference to Fig. 12. At step S11, the following definitions are set: ~~Reference symbol~~ Reference symbol M denotes a message, ~~Reference symbol~~ Reference symbol p denotes a characteristic, ~~Reference symbols~~ Reference symbols a and b denote elliptic curve coefficients (elliptic curve: $y^2 = x^3 + ax + b$), ~~Reference symbol~~ Reference symbol G denotes a base point on the elliptic curve, ~~Reference symbol~~ Reference symbol r denotes the digit of G , ~~and~~ Reference symbols G and $K_s \times G$ denote public keys ($0 < K_s < r$). At step S12, it is verified that the electronic signature data c and d meet $0 < c < r$ and $0 < d < r$. If the data meet these conditions, then at step S13, a hash value for the message M is calculated to obtain $f = \text{Hash}(M)$. Next, at step S14, $h = 1/d \bmod r$ is calculated, and at step S15, $h_1 = fh \bmod r$ and $h_2 = ch \bmod r$ are calculated.

[0404] At step S16, the already calculated values h_1 and h_2 are used to calculate $P = (X_p, Y_p) = h_1 \times G + h_2 \cdot K_s \times G$. An electronic-signature verifier knows the public keys G and $K_s \times G$ and can thus calculate a scalar multiplication of a point on the elliptic curve ~~similarly as to~~ similarly as to step S4 in Fig. 11. Then, at step S17, it is determined whether the P is a point at infinity, ~~and~~ and ~~i~~ i If not, the process proceeds to step S18 (the determination of whether the P is a point at infinity can actually be made at step S16). That is, when $P = (X, Y)$ and $Q = (X, -Y)$ are added together, if the λ cannot be calculated, it indicates ~~ing~~ that $P + Q$ is a point at infinity. At step S18, $X_p \bmod r$ is calculated and compared with the electronic signature data c . Finally, if these values are equal, the

process proceeds to step S19 to determine that the electronic signature is correct.

[0405] If it is determined that the electronic signature is correct, the data has not been tampered with and ~~that~~ a person holding the secret key corresponding to the public keys has generated the electronic signature.

[0406] If the signature data c or d do not meet $0 < c < r$ or $0 < d < r$ at step S12, the process proceeds to step S20. Additionally, if the P is a point at infinity at step S17, the process also proceeds to step S20. Further, if the value of $X_p \bmod r$ does not equal the signature data c at step S18, the process proceeds to step S20.

[0407] If it is determined at step S20 that the signature ~~to be~~ is incorrect, this indicates that the received data ~~have~~has been tampered with or ~~have~~has not been generated by the person holding the secret key corresponding to the public keys.

(3-4) Mutual Authentication Based on Common Key Cryptosystem

[0408] Next, a mutual authentication method using a common key cryptosystem will be explained with reference to Fig. 13. In this figure, the common key cryptosystem is the DES, but any common key cryptosystem similar to that previously described may be used. In Fig. 13, B first generates a 64-bit random number R_b and transmits the R_b and its own ID, $ID(b)$, to A. On receiving ~~the~~ data, the A generates a new 64-bit random number R_a , encrypts the data in the DES CBC mode in the order of the R_a , R_b , and $ID(b)$ using a key K_{ab} , and returns them to ~~the~~ B. According to the DES CBC mode process configuration shown in Fig. 7, the R_a , R_b , and $ID(b)$ correspond to M_1 , M_2 , and M_3 , and outputs E_1 , E_2 , and E_3 are encrypted texts when an initial value: $IV = 0$.

[0409] On receiving the data, ~~the~~ B decrypts the received data with the key K_{ab} . To decrypt the received data, the encrypted ~~test~~text E_1 is first decrypted with the key K_{ab} to obtain the random number R_a . Then, the encrypted ~~test~~text E_2 is decrypted with the key K_{ab} , and the result and ~~the~~ E_1 are exclusive-ORed to obtain the R_b . Finally, the encrypted ~~test~~text E_3 is decrypted with the key K_{ab} , and the result and

~~the~~E2 are exclusive-ORed to obtain the ID(b). Of the Ra, Rb, and ID(b) thus obtained, the Rb and ID(b) are checked for equality to those transmitted by ~~the~~B. If they are successfully verified, ~~the~~B authenticates ~~the~~A.

[0410] Then, ~~the~~B generates a session key (hereafter referred to as "Kses") used after the authentication. Kses ~~(this is generated using a random number)~~. The Rb, Ra, and Kses are encrypted in the DES CBC mode in this order using the key Kab and then returned to ~~the~~A.

[0411] On receiving the data, ~~the~~A decrypts the received data with the key Kab. The method for decrypting the received data is similar to that executed by ~~the~~B, so detailed description thereof is omitted. Of the Rb, Ra, and Kses thus obtained, the Rb and Ra are checked for equality to those transmitted by ~~the~~A. If they are successfully verified, ~~the~~A authenticates ~~the~~B. After ~~the~~A and B have authenticated each other, the session key Kses is used as a common key for secret communication after the authentication.

[0412] If illegality or inequality is found during the verification of the received data, the mutual authentication is considered to have failed and the process is aborted.

(3-5)Public Key Certificate

[0413] Next, the public key certificate will be explained with reference to Fig. 14. The public key certificate is issued, for example, by a Certificate Authority ("CA") for the public key cryptosystem. When a user submits his or her own ID, a public key, and others to the ~~certificate authority~~CA, ~~it~~the CA adds information such as its own ID and valid term to the data submitted by the user and further adds its signature thereto to generate a public key certificate.

[0414] The public key certificate shown in Fig. 14 contains the version number of the certificate, the sequential number of the certificate allotted to the certificate user by the ~~CAcertificate authority~~, an algorithm and parameters used for the electronic signature, the name of the ~~certificate authority~~CA, the valid term of the certificate, the name (user ID) of the certificate user, and the public key and electronic signature of the certificate user.

[0415] The electronic signature is data generated by applying the hash function to the entirety of: the version number of the certificate, the sequential number of the certificate allotted to the certificate user by the certificate authority; the algorithm and parameter used for the electronic signature; the name of the CAcertificate authority; the valid term of the certificate; the name of the certificate user; and the public key of the certificate user. ~~to~~ This generates a hash value. ~~and then using t~~ The secret key of the CAcertificate authority is used for this value. For example, the process flow described in Fig. 11 is applied to the generation of the electronic signature.

[0416] The CAcertificate authority issues the public key certificate shown in Fig. 14, updates a public key certificate for which the valid term has expired, and creates, manages, and distributes an illegal user list to exclude users who has committed an injustice (this is called "revocation"). It also generates public and secret keys as required.

[0417] On the other hand, to use this public key certificate, the user uses the public key of the CAcertificate authority held by itself to verify the electronic signature on the public key certificate. ~~and~~ After the electronic signature has been successfully verified, the user takes the public key out from the public key certificate and uses it. Thus, all users who use the public key certificate must hold a common public key of the CAcertificate authority. The method for verifying the electronic authority has been described in Fig. 12, so detailed description thereof is omitted.

(3-6) Mutual Authentication Based on Public Key Cryptosystem

[0418] Next, a method for mutual authentication using a 160-bit elliptic curve cryptography, which is a public key cryptography, will be described with reference to Fig. 15. In this figure, the public key cryptosystem is the ECC, but any similar public key cryptosystem may be used as previously described. In addition, the key size is not limited to 160 bits. In Fig. 15, ~~the~~ B first generates and transmits the 64-bit random number R_b to ~~the~~ A. On receiving the data, ~~the~~ A generates a new 64-bit random number R_a and a random number A_k

smaller than the characteristic p . It then multiplies a base point G by A_k to determine a point $A_v = A_k \times G$, generates an electronic signature $A. Sig$ for the R_a , R_b , and A_v (X and Y coordinates), and returns these data to ~~the~~ B together with ~~the~~ A 's public key certificate. In this case, since the R_a and R_b each contain 64 bits and the X and Y coordinates of the A_v each contain 160 bits, the electronic signature is for the total of 448 bits. The method for generating the electronic signature has been described in Fig. 11, so detailed description thereof is omitted. The public key certificate has also been explained in Fig. 14, so detailed description thereof is omitted.

[0419] On receiving ~~the~~ A 's public key certificate, R_a , R_b , A_v , and electronic signature $A. Sig$, ~~the~~ B verifies that the R_b transmitted by ~~the~~ A matches that generated by the B . If they are determined to match, ~~the~~ B verifies the electronic signature in ~~the~~ A 's public key certificate using the public key of the CAcertificate authority, and takes out ~~the~~ A 's public key. The verification of the public key certificate has been explained with reference to Fig. 14, so detailed description thereof is omitted. ~~The~~ B then uses ~~the~~ A 's public key obtained to verify the electronic signature $A. Sig$. The method for verifying the electronic signature has been explained in Fig. 12, so detailed description thereof is omitted. Once the electronic signature has been successfully verified, ~~the~~ B authenticates ~~the~~ A .

[0420] Next, ~~the~~ B generates a new random number B_k smaller than the characteristic p . It then multiplies the base point G by B_k to determine a point $B_v = B_k \times G$, generates an electronic signature $B. Sig$ for the R_b , R_a , and B_v (X and Y coordinates), and returns these data to ~~the~~ A together with ~~the~~ B 's public key certificate.

[0421] On receiving ~~the~~ B 's public key certificate, R_b , R_a , A_v , and electronic signature $B. Sig$, ~~the~~ A verifies that the R_a transmitted by ~~the~~ B matches that generated by ~~the~~ A . If they are ~~determined to match~~, ~~the~~ A verifies the electronic signature in ~~the~~ B 's public key certificate using the public key of the CAcertificate authority, and takes out ~~the~~ B 's

public key. ~~The~~A then uses ~~the~~B's public key obtained to verify the electronic signature B. Sig. Once the electronic signature has been successfully verified, ~~the~~A authenticates ~~the~~B.

[0422] If both ~~the~~A and B have successfully authenticated each other, ~~the~~B calculates $B_k \times A_v$ (since the B_k is a random number but the A_v is a point on the elliptic curve, the point on the elliptic curve must be subjected to scalar multiplication), and ~~the~~A calculates $A_k \times B_v$ so that lower 64 bits of each of the X coordinates of these points are used as the session key for subsequent communication (if the common key cryptography uses a 64-bit key length). Of course, the session key may be generated from the Y coordinates, or the lower 64 bits may not be used. In secret communication after the mutual authentication, not only transmitted data are encrypted with the session key, but an electronic signature may be added thereto.

[0423] If illegality or inequality is found during the verification of the electronic signature or received data, the mutual authentication is considered to have failed and the process is aborted.

(3-7) Encryption Process Using Elliptic Curve Cryptography

[0424] Next, encryption using elliptic curve cryptography will be explained with reference to Fig. 16. At step S21, the following definitions are set: ~~Reference~~ symbols M_x and M_y denote messages, ~~Reference~~ symbol p denotes a characteristic, reference symbols a and b denote elliptic curve coefficients (elliptic curve: $y^2 = x^3 + ax + b$), ~~Reference~~ symbol G denotes a base point on the elliptic curve, ~~Reference~~ symbol r denotes the digit of G , and ~~Reference~~ symbols G and $K_s \times G$ denote public keys ($0 < K_s < r$). At step S22, the random number u is generated so that $0 < u < r$. At step S23, coordinates V are calculated by multiplying the public key $K_s \times G$ by the u . The scalar multiplication on the elliptic curve has been explained at step S4 in Fig. 11, and description thereof is thus omitted. At step S24, the X coordinate of the V is multiplied by the M_x and then divided by the p to determine a remainder X_0 . At step S25, the Y

coordinate of the V is multiplied by the M_y and then divided by the p to determine a remainder Y_0 . If the length of the message is smaller than the number of the bits, the M_y comprises a random number, and the decryption section discards it. At step S26, $u \times G$ is calculated and at step S27, an encrypted text $u \times G$, (X_0, Y_0) is obtained.

Decryption Process Using Elliptic Curve Cryptography

[0425] Next, decryption using the elliptic curve ~~cryptograhycryptography~~ will be described with reference to Fig. 17. At step S31, the following definitions are set. ~~Reference symbols~~ $u \times G$ and (X_0, Y_0) denote encrypted text data. ~~Reference symbol~~ p denotes a characteristic. ~~Reference symbols~~ a and b denote elliptic curve coefficients (elliptic curve: $y^2 = x^3 + ax + b$). ~~Reference symbol~~ G denotes a base point on the elliptic curve. ~~Reference symbol~~ r denotes the digit of G . ~~and~~ ~~Reference symbol~~ K_s denotes a secret key ($0 < K_s < r$). At step S32, the encrypted data $u \times G$ are multiplied by a value corresponding to the secret key K_s to determine coordinates $V (X_v, Y_v)$. At step S33, the X coordinate of (X_0, Y_0) is taken out from the encrypted data and $X_1 = X_0 / X_v \bmod p$ is calculated. At step S34, the Y coordinate is taken out and $Y_1 = Y_0 / Y_v \bmod p$ is calculated. At step S35, X_1 is determined to be M_x and Y_1 is determined to be M_y to obtain a message. At this point, if the M_y is not used for the message, Y_1 is discarded.

[0426] In this manner, when the secret key is K_s , the public key is G , and $K_s \times G$ is calculated, the key used for encryption and the key used for decryption may be different.

[0427] Another known example of the public key cryptography is the RSA, but detailed description thereof is omitted (details thereof are described in PKCS #1 Version 2).

Random Number Generating Process

[0428] Next, a method for generating a random number will be explained. Known random-number generating methods include an intrinsic random-number generating method that amplifies thermal noise to generate a random number from the resulting A/D output and a pseudo random-number generating method that combines together a plurality of linear circuits such as M

sequences. A method is also known which uses common key cryptography such as the DES. In this example, the pseudo random-number generating method using the DES will be described (ANSI X9.17 base).

[0429] First, the value of 64 bits (for a smaller number of bits, higher bits are set to 0) obtained from data such as time is defined as D, key information used for the Triple-DES is defined as Kr, and a seed for generating a random number is defined as S. Then, the random number R is calculated as follows:

$I = \text{Triple-DES}(Kr, D) \dots\dots (2-1)$

$I = \text{Triple-DES}(Kr, S \oplus I) \dots\dots (2-2)$

$I = \text{Triple-DES}(Kr, R \oplus I) \dots\dots (2-3)$

[0430] In this case, Triple-DES() is a function that uses a first argument as cryptography key information and ~~that~~ encrypts the value of a second argument based on the Triple-DES. The operation \oplus is an exclusive OR executed every 64 bits. The last value S is updated as a new seed.

[0431] If random numbers are continuously generated, Equations (2-2) and (2-3) are repeated.

[0432] The aspects of various cryptography processes applicable to the data processing apparatus according to the present invention have been described. Next, specific processes executed in the present data processing apparatus will be described in detail.

(4) Configuration of Data Stored in Recording and Reproducing Device

[0433] Fig. 18 is a view ~~useful in explaining~~ illustrating the contents of data held in the internal memory 307 configured in the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 shown in Fig. 3.

[0434] As shown in Fig. 18, the internal memory 307 stores the following keys and data:

MKake: recording device authenticating master key for generating an authentication and key exchange key (hereafter referred to as "Kake") required for a mutual authentication process executed between the recording and reproducing device 300 and recording device 400 (see Fig. 3).

IVake: initial value for the recording device authenticating key.

MKdis: master key for a distribution key for generating a distribution key Kdis.

IVdis: distribution-key-generating initial value.

Kicva: integrity-check-value-A-generating key for generating the integrity check value ICVa.

Kicvb: integrity-check-value-B-generating key for generating the integrity check value ICVb.

Kicvc: content-integrity-check-value-generating key for generating the integrity check value ICVi ($i=1$ to N) for each content block.

Kicvt: total-integrity check value-generating key for generating the total integrity check value ICVt.

Ksys: system signature key used to add a common signature or ICV to a distribution system.

Kdev: recording and reproducing device signature key that varies depending on recording and reproducing device and that is used by the recording and reproducing device to add a signature or ICV.

IVmem: initial value that is used for a cryptography process for mutual authentication, or the like. This is shared by the recording device.

[0435] These keys and data are stored in the internal memory 307 configured in the recording and reproducing device cryptography process section 302.

(5) Configuration of Data Stored in Recording Device

[0436] Fig. 19 is a view showing how data are held on the recording device 400. In this figure, the internal memory 405 is divided into a plurality of (in this example, N) blocks each storing the following keys and data:

IDmen: recording device identification information that is unique to the recording device 400.

Kake: authentication key that is used for mutual authentication with the recording and reproducing device 300.

IVmem: initial value that is used for a cryptography process for mutual authentication, or the like.

Kstr: storage key that is a cryptography key for the block information table and other content data.

Kr: random number generating key.

S: seed.

[0437] These data are each held in the corresponding block. An external memory 402 holds a plurality of (in this example, M) content data. ~~It~~ It holds the data described in Fig. 4 as shown, for example, in Fig. 26 or 27. The difference in configuration between Figs. 26 and 27 will be described later.

(6) Mutual Authentication Process ~~Between~~ Between ~~Recording and~~ Reproducing Device and Recording Device

(6-1) Outline of Mutual Authentication Process

[0438] Fig. 20 is a flow chart ~~showing~~ illustrating a procedure for an authentication between the recording and reproducing device 300 and the recording device 400. At step S41, the user inserted the recording device 400 into the recording and reproducing device 300. If, however, the recording device 400 is capable of communication in a non-contact manner, it need not be inserted thereinto.

[0439] When the recording device 400 is set in the recording and reproducing device 300, a recording device detecting means (not shown) in the recording and reproducing device 300 shown in Fig. 3 notifies the control section 301 that the recording device 400 has been installed. Then at step S42, the control section 301 of the recording and reproducing device 300 transmits an initialization command to the recording device 400 via the recording device controller 303. On receiving the command, the recording device 400 causes the control section 403 of the recording device cryptography process section 401 to receive the command via the communication section 404 and clear an authentication

completion flag if it has been set. That is, an unauthenticated state is set.

[0440] Then at step S43, the control section 301 of the recording and reproducing device 300 transmits an initialization command to the recording and reproducing device cryptography process section 302. At this point, it also transmits a recording device insertion port number. When the recording device insertion port number is transmitted, even if a plurality of recording devices 400 are connected to the recording and reproducing device 300, the recording and reproducing device 300 can simultaneously execute authentication with these recording devices 400 and transmit and receive data thereto and therefrom.

[0441] On receiving the initialization command, the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 causes the control section 306 thereof to clear the authentication complete flag corresponding to the recording device insertion port number if it has been set. That is, the unauthenticated state is set.

[0442] Then at step S44, the control section 301 of the recording and reproducing device 300 specifies a key block number used by the recording device cryptography process section 401 of the recording device 400. Details of the key block number will be described later. At step S45, the control section 301 of the recording and reproducing device 300 reads out the recording device identification information IDmem stored in the specified key block in the internal memory 405 of the recording device 400. At step S46, the control section 301 of the recording and reproducing device 300 transmits the recording device identification information IDmem to the recording and reproducing device cryptography process section 302 to generate the authentication key Kake based on the recording device identification information IDmem. The authentication key Kake is generated, for example, as follows:

$$Kake = DES(MKake, IDmem \oplus IVake) \dots\dots(3)$$

[0443] In this case, the MKake denotes the master key for the recording device authentication key used to generate the authentication key Kake required for the mutual authentication process executed between the recording and reproducing device 300 and the recording device 400 (see Fig. 3). ~~the~~ The master key ~~being~~ can be stored in the internal memory 307 of the recording and reproducing device 300 as described above. Additionally, the IDmem denotes the recording device identification information unique to the recording device 400. Furthermore, the IVake denotes the initial key for the recording device authentication key. In addition, in the above equation, the DES() denotes a function that uses a first argument as cryptography key and ~~that~~ encrypts the value of a second argument based on the DES. The operation \oplus denotes an exclusive OR executed every 64 bits.

[0444] If, for example, the DES configuration shown in Fig. 7 or 8 is applied, the message M shown in Figs. 7 and 8 corresponds to the recording device identification information: IDmem, the key K1 corresponds to the master key for the device authentication key: MKake, the initial value IV corresponds to the value: IVake, and the output obtained is the authentication key Kake.

[0445] Then at step S47, the mutual authentication process and the process for generating the session key Kses are carried out. The mutual authentication is executed between the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 and the encryption/decryption section 406 of the recording device cryptography process section 401; the control section 301 of the recording and reproducing device 300 mediates therebetween.

[0446] The mutual authentication process can be executed as previously described in Fig. 13. In the configuration shown in Fig. 13, ~~the~~ A and B correspond to the recording and reproducing device 300 and the recording device 400, respectively. First, the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 generates the random number Rb and

transmits the Rb and the recording and reproducing device identification information IDdev, which is its own ID, to the recording device cryptography process section 401 of the recording device 400. The recording and reproducing device identification information IDdev is an identifier unique to a reproducing device stored in a memory section configured in the recording and reproducing device 300. The recording and reproducing device identification information IDdev may be recorded in the internal memory of the recording and reproducing device cryptography process section 302.

[0447] On receiving the ~~random~~ random number Rb and the recording and reproducing device identification information IDdev, the recording device cryptography process section 401 of the recording device 400 generates a new 64-bit random number Ra, encrypts the data in the DES CBC mode in the order of the Ra, Rb, and recording and reproducing device identification information IDdev using the authentication key Kake, and returns them to the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300. For example, according to the DES CBC mode process configuration shown in Fig. 7, the Ra, Rb, and IDdev correspond to the M1, M2, and M3, respectively, and when the initial value \div IV=IVmem, the outputs E1, E2, and E3 are encrypted texts.

[0448] On receiving the encrypted texts E1, E2, and E3, the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 decrypts the received data with the authentication key Kake. To decrypt the received data, the encrypted text E1 is first decrypted with the key Kake and the result and the IVmem are exclusive-ORed to obtain the random number Ra. Then, the encrypted text E2 is decrypted with the key Kake, and the result and the E1 are exclusive-ORed to obtain the Rb. Finally, the encrypted text E3 is decrypted with the key Kake, and the result and the E2 are exclusive-ORed to obtain the recording and reproducing device identification information IDdev. Of the Ra, Rb, and recording and reproducing device identification information IDdev thus obtained, the Rb and recording and reproducing

device identification information IDdev are checked for equality to those transmitted by the recording and reproducing device 300. If they are successfully verified, the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 authenticates the recording device 400.

[0449] Then, the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 generates a session key (hereafter referred to as "Kses") used after the authentication. ~~(this Kses is generated using a random number)~~. The Rb, Ra, and Kses are encrypted in the DES CBC mode in this order using the key Kake and the initial value IVmem and then returned to the recording device cryptography process section 401 of the recording device 400.

[0450] On receiving the data, the recording device cryptography process section 401 of the recording device 400 decrypts the received data with the key Kake. The method for decrypting the received data is similar to that executed by the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300, so detailed description thereof is omitted. Of the Ra, Rb, and Kses thus obtained, the Rb and Ra are checked for equality to those transmitted by the recording device 400. If they are successfully verified, the recording device cryptography process section 401 of the recording device 400 authenticates the recording and reproducing device 300. After these devices have authenticated each other, the session key Kses is used as a common key for secret communication after the authentication.

[0451] If illegality or inequality is found during the verification of the received data, the mutual authentication is considered to have failed and the process is aborted.

[0452] If the mutual authentication has been successful, the process proceeds from step S48 to step S49 where the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 holds the session key Kses and where the authentication complete flag is set, indicating that the mutual authentication has been

completed. Additionally, if the mutual authentication has failed, the process proceeds to step S50, the session key Kses is discarded and the authentication complete flag is cleared. If the flag has already been cleared, the clearing process is not necessarily required.

[0453] If the recording device 400 is removed from the recording device insertion port, the recording device detecting means in the recording and reproducing device 300 notifies the control section 301 of the recording and reproducing device 300 that the recording device 400 has been removed. In response to this, the control section 301 of the recording and reproducing device 300 commands the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 to clear the authentication complete flag corresponding to the recording device insertion port number. In response to this, the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 clears the authentication complete flag corresponding to the recording device insertion port number.

[0454] The example has been described where the mutual authentication process is executed in accordance with the procedure shown in Fig. 13, but the present invention is not limited to the above described example of authentication process. ~~but~~ The process may be executed, for example, in accordance with the above described mutual authentication procedure in Fig. 15. Alternatively, in the procedure shown in Fig. 13, ~~the~~ A in Fig. 13 may be set as the recording and reproducing device 300, ~~the~~ B may be set as the recording device 400, and the ID that ~~the~~ B: recording device 400 first delivers to ~~the~~ A: recording and reproducing device 300 may be set as the recording device identification information in the key block in the recording device 400. Various processes are applicable to the authentication process procedure executed in the present invention, and the present invention is not limited to the above described authentication process.

(6-2) Switching Key Block ~~d~~ During Mutual Authentication

[0455] The mutual authentication process in the data processing apparatus according to the present invention is partly characterized in that the authentication process is executed by configuring a plurality of (for example, N) key blocks on the recording device 400 side and allowing the recording and reproducing device 300 to specify one of them (step S44 in the process flow in Fig. 20). As previously described in Fig. 19, the internal memory 405 configured in the cryptography process section 401 of the recording device 400 has a plurality of key blocks formed therein which store various different data such as key data and ID information. The mutual authentication process executed between the recording and reproducing device 300 and the recording device 400 as described in Fig. 20 is carried out on one of the plurality of key blocks of the recording device 400 in Fig. 19.

[0456] Conventional configurations for executing a mutual authentication process between a recording medium and a reproducing device therefor generally use a common authentication key for the mutual authentication. Thus, when the authentication key is to be changed for each product destination (e.g., country) or each product, key data required for authentication processes for the recording and reproducing device side and the recording device side must be changed on both devices. Accordingly, key data required for an authentication process stored in a newly sold recording and reproducing device 300 does not correspond to key data required for an authentication process stored in a previously sold recording and reproducing device 300, so the new —recording and reproducing device 300 cannot access an old version of recording device 400. ~~On contrary, a~~ similar situation occurs in the relationship between a new version of recording device 400 and the old version of recording and reproducing device 300.

[0457] In the data processing apparatus according to the present invention, key blocks are stored in the recording device 400 as a plurality of different key sets as shown in Fig. 19. The recording and reproducing device 300 has a key block to be applied to the authentication process. ~~That is,~~

a specified key block set, for example, for each product destination (e.g., country), product, device type, version, or application. This set information is stored in the memory section of the recording and reproducing device 300, for example, the internal memory 307 in Fig. 3 or other storage elements of the recording and reproducing device 300., ~~and~~ It is accessed by the control section 301 ~~in Fig. 3~~ during the authentication process to specify a key block in accordance therewith.

[0458] The master key Mmake for the recording device authentication key in the internal memory 307 of the recording and reproducing device 300 is set in accordance with settings for a specified key block and can correspond only to that specified key block. ~~It~~ It does not establish mutual authentication with any key blocks other than the specified one.

[0459] As is seen in Fig. 19, the internal memory 405 of the recording device 400 has N key blocks (1 to N) set. ~~which~~ Each store recording device identification information, an authentication key, an initial value, a storage key, a random-number generating key, and a seed. ~~e~~ Each key block stores at least authenticating key data as data varying depending on the block.

[0460] In this manner, the key data configuration of the key block in the recording device 400 varies depending on the block. Thus, for example, a key block with which a certain recording and reproducing device A can execute the authentication process using the master key Mmake for the recording device authentication key stored in the internal memory can be set as a key block No. 1, and a key block with which a recording and reproducing device B with a different specification can execute the authentication process can be set as another key block, for example, a key block No. 2.

[0461] Although described later in detail, when a ~~content~~ content is stored in the external memory 402 of the recording device 400, the storage key Kstr stored in each key block is used to encrypt and store the content. More specifically, the storage

key is used to encrypt a content key for encrypting a content block.

[0462] As shown in Fig. 19, the storage key is configured as a key that varies depending on the block. Thus, a content stored in a memory of a recording device is prevented from being shared by two different recording and reproducing devices 300 set to specify different key blocks. That is, differently set recording and reproducing devices 300 can each use only the contents stored in a recording device 400 that is compatible with its settings.

[0463] Data that can be made common to each key block can be made so, while, for example, only the authenticating key data and the storage key data may vary depending on the key block.

[0464] In a specific example where key blocks comprising a plurality of different key data are configured in the recording device 400, for example, different key block numbers to be specified are set for different types of recording and reproducing devices 300 (e.g., an installed type, a portable type, and the like), or different specified key blocks are set for different applications. Furthermore, different key blocks may be set for different territories. ~~For example,~~ For example, the key block No. 1 is specified for recording and reproducing devices 300 sold in Japan, and the key block No. 2 is specified for recording and reproducing devices 300 sold in the U.S. With such a configuration, a content that is used in different territories and that is stored in each recording device 400 with a different storage key cannot be used in a recording and reproducing device 300 with different key settings even if a recording device 400 such as a memory card is transferred from the U.S. to Japan or vice versa, thereby preventing the illegal or disorderly distribution of the content stored in the memory. Specifically, this serves to exclude a state where a content key Kcon encrypted with different storage keys Kstr can be mutually used in two different countries.

[0465] Moreover, at least one of the key blocks 1 to N in the internal memory 405 of the recording device 400 shown in

Fig. 19, (for example, the No. N key block) may be shared by any recording and reproducing device 300.

[0466] For example, when the key block No. N and the master key MKake for the recording device authentication key, (which is capable of authentication), are stored in all apparatuses, contents can be distributed irrespective of the type of the recording and reproducing device 300, the type of the application, or the ~~destined~~destination country. For example, ~~an~~ encrypted content stored in a memory card with the storage key stored in the key block No. N can be used in any apparatuses. ~~For example, m~~Music data or the like can be decrypted and reproduced from a memory card by encrypting the data with the storage key in a shared key block, storing them in the memory card, and setting the memory card in, for example, a portable sound reproducing device storing the master key MKake for the recording device authentication key, which is also shared.

[0467] Fig. 21 shows an example of the usage of the recording device of the present data processing apparatus, which has a plurality of key blocks. For instance, aA recording and reproducing device 2101 is a product sold in Japan and has a master key that establishes an authentication process with the key blocks No. 1 and No. 4 in the recording device. A recording and reproducing device 2102 is a product sold in the U.S. and has a master key that establishes an authentication process with the key blocks No. 2 and No. 4 in the recording device. A recording and reproducing device 2103 is a product sold in the EU and has a master key that establishes an authentication process with the key blocks No. 3 and No. 4 in the recording device.

[0468] For example, the recording and reproducing device 2101 establishes authentication with the key block 1 or 4 in the recording device A 2104 to store, in the external memory, contents encrypted via the storage key stored in that key block. The recording and reproducing device 2102 establishes authentication with the key block 2 or 4 in the recording device B 2105 to store, in the external memory, contents encrypted via the storage key stored in that key block. The

recording and reproducing device 2103 establishes authentication with the key block 3 or 4 in the recording device C 2106 to store, in the external memory, contents encrypted via the storage key stored in that key block. Then, if the recording device A 2104 is installed in the recording and reproducing device 2102 or 2103, a—content encrypted with the storage key in the key block 1 is unavailable because authentication is not established between the recording and reproducing device 2102 or 2103 and the key block 1. On the other hand, a—content encrypted with the storage key in the key block 4 is available because authentication is established between the recording and reproducing device 2102 or 2103 and the key block 4.

[0469] As described above, in the data processing apparatus according to the present invention, the key blocks comprising the plurality of different key sets are configured in the recording device 400, while the recording and reproducing device 300 stores the master key enabling authentication for a particular key block, thereby enabling the setting of restrictions on ~~the use of contents~~ use depending on different use form.

[0470] Moreover, a plurality of key blocks, for example, 1 to k may be specified in one recording and reproducing device 300, while a plurality of key blocks p and q may be specified in the other recording and reproducing devices 300. Additionally, a plurality of sharable key blocks may be provided.

(7) Process for Downloading from Recording and Reproducing Device to Recording Device

[0471] Next, a process for downloading a—content from the recording and reproducing device 300 to the external memory of the recording device 400 in the present data processing apparatus will be explained.

[0472] Fig. 22 is a flow chart ~~useful~~ explaining illustrating a procedure for downloading a content from the recording and reproducing device 300 to the recording device 400. In this figure, the above described mutual

authentication process is assumed to have been completed between the recording and reproducing device 300 and the recording device 400.

[0473] At step S51, the control section 301 of the recording and reproducing device 300 uses the read section 304 to read data of a predetermined format out from the medium 500 storing contents or uses the communication section 305 to receive data from the communication means 600 in accordance with a predetermined format. Then, the control section 301 of the recording and reproducing device 300 transmits the header section (see Fig. 4) of the data to the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300.

[0474] Next, at step S52, the control section 306 of the recording and reproducing device cryptography process section 302, which has received the header at step S51, causes the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 to calculate the ~~ICV~~integrity-check-value-A. The ~~ICV~~integrity-check-value-A is calculated in accordance with the ICV calculation method described in Fig. 7, using as a key the integrity-check-value-A-generating key Kicva stored in the internal memory 307 of the recording and reproducing device cryptography process section 302 and using the content ID and the usage policy as a message, as shown in Fig. 23. The initial value may be IV = 0 or may be the integrity-check-value-A-generating initial value IVa may be used which is stored in the internal memory 307 of the recording and reproducing device cryptography process section 302. Finally, the integrity check value A and the check value: ICVa stored in the header are compared together, and if they are equal, the process proceeds to step S53.

[0475] As previously described in Fig. 4, the check value A, ICVa, is used to verify that the content ID and the usage policy have not been tampered with. If the integrity check value A calculated in accordance with the ICV calculation method described in Fig. 7, equals the check value ICVa stored in the header, it is determined that the content ID and the

~~usage policy have not been tampered with. using as a key the integrity-check-value-A-generating key Kicva stored in the internal memory 307 of the recording and reproducing device cryptography process section 302 and using the content ID and the usage policy as a message, equals the check value: ICVa stored in the header, it is determined that the content ID and the usage policy have not been tampered. The integrity check value A from one method in Fig. 7 uses, as a key, the integrity-check-value-A-generating key Kicva stored in the internal memory 307. It uses the content ID and the usage policy as a message.~~

[0476] Next, at step S53, the control section 306 of the recording and reproducing device cryptography process section 302 causes the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 to generate the distribution key Kdis. The distribution key Kdis is generated, for example, as follows:

$$Kdis = DES(MKdis, ContentID \oplus IVdis) \quad \dots\dots (4)$$

[0477] In this case, the MKdis denotes the master key for the distribution key for generating the distribution key Kdis, ~~t~~ The master key being can be stored in the internal memory 307 of the recording and reproducing device 300 as described above. In addition, the content ID is identification information for the header section of content data, ~~and t~~ The IVdis denotes the initial value for the distribution key. Additionally, in the above equation (4), the DES() denotes a function that uses a first argument as cryptography key and that encrypts the value of a second argument. The operation \oplus denotes an exclusive OR executed every 64 bits.

[0478] At step S54, the control section 306 of the recording and reproducing device cryptography process section 302 uses the encryption/decryption section 308 of the ~~recording and reproducing device cryptography process section 302,~~ as well as the distribution key Kdis generated at step S53, to decrypt the block information table key Kbit and content key Knon (see Fig. 4). Kbit and Kdis are stored in the

header section of the data obtained from the medium 500 via the read section 304 or received from the communication means 600 via the communication section 305. As shown in Fig. 4, the block information table key Kbit and the content key Kcon are encrypted beforehand with the distribution key Kdis on the medium 500, such as a DVD or CD, or on a communication ~~path~~means 600 such as the Internet.

[0479] Further, at step S55, the control section 306 of the recording and reproducing device cryptography process section 302 uses the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 to decrypt the block information table (BIT) with the block information table key Kbit decrypted at step S54. The block information table (BIT), as shown in Fig. 4, is encrypted beforehand with the block information table key Kbit on the medium 500 such as the DVD or CD, or the communication ~~path~~means 600 such as the Internet.

[0480] Further, at step S56, the control section 306 of the recording and reproducing device cryptography process section 302 divides the block information table key Kbit, the content key Kcon, and the block information table (BIT) into 8-byte pieces, which are all exclusive-ORed (any operation such as an addition or subtraction may be used). Next, the control section 306 of the recording and reproducing device cryptography process section 302 causes the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 to calculate the integrity check value B (ICVb). The ~~ICVb~~integrity-check-value-B is generated by using as a key the integrity-check-value-B-generating key Kicvb stored in the internal memory 307 of the recording and reproducing device cryptography process section 302. This is done to decrypt the previously calculated exclusive-ORed value based on the DES, as shown in Fig. 24. Finally, the integrity check value B and the ICVb in the header are compared together, and if they are equal, the process proceeds to step S57.

[0481] As previously described in Fig. 4, the check value B, ICVb is used to verify that the block information table key

Kbit, the content key Kcon, and the block information table (BIT) have not been tampered with. If the integrity check value B generated by using as a key the integrity check value-B-generating key Kicvb stored in the internal memory 307 of the recording and reproducing device cryptography process section 302, dividing the block information table key Kbit, the content key Kcon, and the block information table (BIT) into 8-byte pieces, exclusive-Oring these data, and encrypting the exclusive-ORed data based on the DES, equals the check value ICVb stored in the header, it is determined that the block information table key Kbit, the content key Kcon, and the block information table have not been tampered with. The integrity check value B is generated by using, as a key, the integrity-check-value-B-generating key Kicvb stored in the internal memory 307, dividing the block information table key Kbit, the content key Kcon, and the block information table (BIT) into 8-byte pieces; exclusive-Oring these data; and encrypting the exclusive-ORed data based on the DES.

[0482] At step S57, the control section 306 of the recording and reproducing device cryptography process section 302 causes the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 to calculate an intermediate integrity check value. The intermediate value is calculated in accordance with the ICV calculation method described in Fig. 7. This is done using as a key the total-integrity-check-value generating key Kicvt as a key. The key is stored in the internal memory 307 of the recording and reproducing device cryptography process section 302, and using and uses the integrity check values A and B and all the held content integrity check values as a message. The initial value may be IV=0 or the total-integrity-check-value-generating initial value IVt may be used. IVt which is stored in the internal memory 307 of the recording and reproducing device cryptography process section 302. Additionally, the intermediate integrity check value generated is stored in the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300, as required.

[0483] This intermediate integrity check value is generated using the integrity check values A and B and all the content integrity check values as a message, ~~and a~~ Data verified by each of these integrity check values may be verified by collating them with the intermediate integrity check value. In this embodiment, however, a plurality of different integrity check values, ~~that is, total integrity check values ICVt and the check value ICVdev unique to the recording and reproducing device 300~~ can be separately generated based on the intermediate integrity check value. This is done so that the process for verifying the absence of tamper which process is executed for shared data for the entire system and the verification process for identifying occupied data occupied only by each recording and reproducing device 300 after the download process can be distinguishably executed. The plurality of different integrity check values are, for instance, total integrity check values ICVt and the check value ICVdev unique to the recording and reproducing device 300. These integrity check values will be described later.

[0484] The control section 306 of the recording and reproducing device cryptography process section 302 causes the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 to calculate the total integrity check value ICVt. The total integrity check value ICVt is generated by using as a key a system signature key Ksys to decrypt the intermediate integrity check value based on the DES. Ksys can be stored in the internal memory 307 of the recording and reproducing device cryptography process section 302. ~~to decrypt the intermediate integrity check value based on the DES.~~ Finally, the total integrity check value ICVt generated and the ICVt in the header stored at step S51 are compared together, and if they are equal, the process proceeds to step S58. The system signature key Ksys is common to a plurality of recording and reproducing devices 300, that is, the entire system executing the process of recording and reproducing certain data.

[0485] As previously described in Fig. 4, the total integrity check value ICVt is used to verify that all of the

integrity check values ICVa and ICVb and the integrity check value for each content block have not been tampered with. Thus, if the total integrity check value generated by means of the above—described process equals the integrity check value+ICVt, stored in the Hheader, it is determined that all of the integrity check values ICVa and ICVb and the integrity check value for each content block have not been tampered with.

[0486] Then at step S58, the control section 301 of the recording and reproducing device 300 takes content block information out from the block information table (BIT) and checks whether any content block is to be verified. If any content block is to be verified, the content integrity check value has been stored in the block information in the header.

[0487] If any content block is to be verified, the control section 301 reads this content block out from the medium 500 by using the read section 304 of the recording and reproducing device 300 or received from communicating means 600 by using the communication section 305 of the recording and reproducing device 300. ~~and~~ Control section 301 transmits the content block to the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300. On receiving the content block, the control section 306 of the recording and reproducing device cryptography process section 302 causes the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 to calculate the content intermediate value.

[0488] The content intermediate value is generated by using the content key Kcon decrypted at step S54 to decrypt an input content block in the DES CBC mode, separating the resulting data into 8-byte pieces, and exclusive-ORing all these pieces (any operation such as an addition or subtraction may be used).

[0489] Then, the control section 306 of the recording and reproducing device cryptography process section 302 causes the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 to calculate the content integrity check value. The content integrity check value is generated by using as a key the content-integrity-check-value-generating key Kicvc ~~stored in~~

~~the internal memory 307 of the recording and reproducing device cryptography process section 302,~~ to decrypt the content intermediate value based on the DES. Kicvc is stored in the internal memory 307 of the recording and reproducing device cryptography process section 302. Then, the control section 306 of the recording and reproducing device cryptography process section 302 compares this content integrity check value with the ICV in the content block received from the control section 301 of the recording and reproducing device 300 at step S51.~~7~~ and It then passes the result to the control section 301 of the recording and reproducing device 300. On receiving the result, and if the verification has been successful, the control section 301 of the recording and reproducing device 300 takes out the next content block to be verified and causes the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 to verify this content block. Similar verification processes are repeated until all the content blocks are verified. The initial value may be IV=0 or the content-integrity-check-value-generating initial value IVC used may be ~~used~~ that which is stored in the internal memory 307 of the recording and reproducing device cryptography process section 302, (if the header generating side uses the same settings). Additionally, all the checked content integrity check values are held in the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300. Furthermore, the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 monitors the order in which the content blocks are verified. This is done to consider whether the authentication has to have failed (if the order is incorrect) or if it ~~is caused to verify~~ sy the same content block twice or more. If all the content blocks have been successfully verified, the process proceeds to step S59.

[0490] Then at step S59, the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 causes the encryption/decryption

section 308 of the recording and reproducing device cryptography process section 302 to encrypt the block information table key Kbit and content key Kcon decrypted at step S54.~~7~~ This is done using the session key Kses made sharable during the mutual authentication. The control section 301 of the recording and reproducing device 300 reads the block information table key Kbit and content key Kcon from the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300.~~7~~~~t~~ The block information table key Kbit and content key Kcon being decrypted using the session key Kses. The control section 301 then transmits these data to the recording device 400 via the recording device controller 303 of the recording and reproducing device 300.

[0491] Then at step S60, on receiving the block information table key Kbit and content key Kcon transmitted from the recording and reproducing device 300, the recording device 400 causes the encryption/decryption section 406 of the recording device cryptography process section 401 to decrypt the received data using the session key Kses. Kses is made sharable during the mutual authentication.~~and~~~~to~~ Encryption/decryption section 406 reencrypts the decrypted data with the storage key Kstr, which is unique to the recording device ~~which~~and is stored in the internal memory 405 of the recording device cryptography process 401. Finally, the control section 301 of the recording and reproducing device 300 reads the block information key Kbit and the content key Kcon out from the recording device 400 via the recording device controller 303 of the recording and reproducing device 300.~~7~~~~t~~ The block information key Kbit and the content key Kcon ~~being~~can be reencrypted with the storage key Kstr. These are then substituted with the block information key Kbit and content key Kcon encrypted with the distribution key Kdis.

[0492] At step S61, the control section 301 of the recording and reproducing device 300 takes the localization field out from the usage policy in the header section of the data to determine whether the downloaded content can be used only in this recording and reproducing device 300 (in this

case, the localization field is set to 1) or also by other similar recording and reproducing devices 300 (in this case, the localization field is set to 0). If the result of the determination shows that the localization field is set to 1, the process proceeds to step S62.

[0493] At step S62, the control section 301 of the recording and reproducing device 300 causes the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 to calculate the integrity check value unique to the recording and reproducing device 300. The integrity check value unique to the recording and reproducing device 300 is generated by using as a key a recording and reproducing device signature key Kdev ~~stored in the internal memory 307 of the recording and reproducing device cryptography process section 302,~~ to decrypt the intermediate integrity check value based on the DES, the intermediate integrity check value being held at step S58. Kdev is stored in the internal memory 307. The calculated integrity check value ICVdev unique to the recording and reproducing device 300 substitutes for the total integrity check value ICVt.

[0494] As previously described, the system signature key Ksys is used to add a common signature, or ICV, to the distribution system. and ~~the~~ The recording and reproducing device 300 signature key Kdev varies depending on the recording and reproducing device 300 and is used by the recording and reproducing device to add a signature or ICV. That is, data signed with the system signature key Ksys are successfully checked by a system (recording and reproducing device 300) having the same system signature key. that is Specifically, such data have the same total integrity check value ICVt so as to be sharable. If, however, data ~~are~~ is signed with the recording and reproducing device signature key Kdev, ~~since this signature key is unique to the recording and reproducing device, the data signed with the recording and reproducing device signature key Kdev, that is,~~ the data stored in a recording device after the signing cannot be reproduced if an attempt is made to reproduce it ~~them~~ after

this recording device has been inserted in another recording and reproducing device 300. That is, an error occurs due to the unequal integrity check values ICVdev unique to the recording and reproducing device 300.

[0495] Thus, in the data processing apparatus according to the present invention, the setting of the localization field enables contents to be arbitrarily set so as to be shared throughout the entire system or used only by particular recording and reproducing devices 300.

[0496] At step S63, the control section 301 of the recording and reproducing device 300 stores the content in the external memory 402 of the recording device 400.

[0497] Fig. 26 is a view showing how the content is stored in the recording device 400 if the localization field is set to 0. Fig. 27 is a view showing how the content is stored in the recording device 400 if the localization field is set to 1. ~~Only~~ The only difference between Figs. 26 and 4 is whether the content block information key Kbit and the content key Kcon are encrypted with the distribution key Kdis or the storage key Kstr. The ~~difference~~ between Figs. 27 and 26 is that the integrity check value calculated from the intermediate integrity check value is encrypted with the system signature key Ksys in Fig. 26, whereas it is encrypted with the recording and reproducing device signature key Kdev unique to the recording and reproducing device 300 in Fig. 27.

[0498] In the process flow ~~in~~ of Fig. 22, if the verification of the integrity check value A has failed at step S52, if the verification of the integrity check value B has failed at step S56, if the verification of the total integrity check value ICVt has failed at step S57, or if the verification of the content block content integrity check value has failed at step S58, then the process proceeds to step S64 to provide a predetermined error display because the verification is no good.

[0499] In addition, if the localization field is 0 at step S61, the process skips step S62 to advance to step S63.

(8) Process Executed by Recording and Reproducing Device to Reproduce Information Stored in Recording Device

[0500] Next, a process executed by the recording and reproducing device 300 to reproduce content information stored in the external memory 402 of the recording device 400 is analyzed.

[0501] Fig. 28 ~~is a flow chart useful in explaining~~ illustrates a procedure executed by the recording and reproducing device 300 to read ~~a content~~ out from the recording device 400 ~~and use it.~~ In Fig. 28, the mutual authentication is assumed to have been completed between the recording and reproducing device 300 and the recording device 400.

[0502] At step S71, the control section 301 of the recording and reproducing device 300 uses the recording device controller 303 to read the content out from the external memory 402 of the recording device 400. The control section 301 of the recording and reproducing device 300 then transmits the header section of the data to the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300. Step S72 is similar to step S52 described in "(7) Process for Downloading from Recording and Reproducing Device to Recording Device." ~~At this step,~~ At this step, the control section 306 of the recording and reproducing device cryptography process section 302, which has received the header, causes the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 to calculate the integrity check value A. The integrity check value A is calculated in accordance with an ICV calculation method similar to that described in Fig. 7, using, as a key, the integrity-check-value-A-generating key Kicva and using the content ID and the usage policy as a message, as shown in Fig. 23. Kicva can be ~~stored in the internal memory 307 of the recording and reproducing device cryptography process section 302, and using the content ID and the usage policy as a message, as shown in the previously described Fig. 23.~~

[0503] As previously described, the check value A, ICVa, is used to verify that the content ID and the usage policy have not been tampered with. If the integrity check value A calculated in accordance with the ICV calculation method described in Fig. 7, ~~using as a key the integrity-check-value-A-generating key Kicva stored in the internal memory 307 of the recording and reproducing device cryptography process section 302 and using the content ID and the usage policy as a message,~~ equals the check value ICVa stored in the header, it is determined that the content ID and usage policy stored in the recording device 400 have not been tampered with. Integrity check value A is calculated using, as a key, the integrity-check-value-A-generating key Kicva stored in the internal memory 307 and using the content ID and the usage policy as a message.

[0504] Then at step S73, the control section 301 of the recording and reproducing device 300 takes the block information table key Kbit and the content key Kcon out from the read-out header section, ~~and~~ It then transmits them to the recording device 400 via the recording device controller 303 of the recording and reproducing device 300. On receiving the block information table key Kbit and the content key Kcon transmitted from the recording and reproducing device 300, the recording device 400 causes the encryption/decryption section 406 of the recording device cryptography process section 401 to decrypt the received data with the storage key Kstr, ~~unique to the recording device which is stored in the internal memory 405 of the recording device cryptography process 401 and to then reencrypt the decrypted data using the session key Kses made sharable during the mutual authentication.~~ Kstr is unique to the recording device which is stored in the internal memory 405. Then, the control section 301 of the recording and reproducing device 300 reads the block information key Kbit and the content key Kcon out from the recording device 400 via the recording device controller 303 of the recording and reproducing device 300. ~~to~~ The block information key Kbit and the content key Kcon being can be reencrypted with the session key Kses from the recording device 400.

[0505] Then at step S74, the control section 301 of the recording and reproducing device 300 transmits the received block information key Kbit and content key Kcon to the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300. ~~The block information key Kbit and content key Kcon being~~ can be reencrypted with the session key Kses.

[0506] On receiving the block information key Kbit and content key Kcon reencrypted with the session key Kses, the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 causes the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 to decrypt the block information key Kbit and content key Kcon encrypted with the session key Kses. This is done using the session key Kses made sharable during the mutual authentication. The recording and reproducing device cryptography process section 302 then causes the encryption/decryption section 308 to decrypt the block information table received at step S71. This is done using the decrypted block information table key Kbit.

[0507] The recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 substitutes the decrypted block information table key Kbit, content key Kcon, and block information table BIT with those received at step S71 for retention. In addition, the control section 301 of the recording and reproducing device 300 reads the decrypted block information table BIT out from the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300.

[0508] ~~At~~ Step S75 is similar to step S56 described in "(7) Process for Downloading from Recording and Reproducing Device to Recording Device." The control section 306 of the recording and reproducing device cryptography process section 302 divides the block information table key Kbit, content key Kcon, and block information table (BIT) read out from the recording device 400, into 8-byte pieces and then exclusive-ORs all of them. The control section 306 of the recording and

reproducing device cryptography process section 302 then causes the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 to calculate ~~the integrity check value B{ICVb}~~. ICVb~~The integrity check value B~~ is generated by using as a key the integrity-check-value-B-generating key Kicvb stored in the internal memory 307 of the recording and reproducing device cryptography process section 302, ~~to encrypt the previously calculated exclusive-ORed value based on the DES,~~ as shown in the previously described Fig. 24. This is done to encrypt the previously calculated exclusive-ORed value based on the DES. Finally, the check value B and the ICVb in the header are compared together, and if they are equal, the process proceeds to step S76.

[0509] As previously described, the check value B, ICVb, is used to verify that the block information table key Kbit, the content key Kcon, and the block information table have not been tampered with. If the integrity check value B generated by using as a key the integrity-check-value-B-generating key Kicvb ~~stored in the internal memory 307 of the recording and reproducing device cryptography process section 302,~~ dividing the block information table key Kbit, the content key Kcon, and the block information table (BIT) read from the recording device 400 into 8-byte pieces, exclusive-Oring these data, and encrypting the exclusive-ORed data based on the DES, equals the check value ~~ICVb~~ stored in the header of the data read out from the recording device 400, it is determined that the block information table key Kbit, the content key Kcon, and the block information table have not been tampered with. Kicvb is stored in the internal memory 307. The block information table key Kbit, the content key Kcon, and the block information table (BIT) read from the recording device 400 are divided into 8-byte pieces. this data is exclusive-ORed. The exclusive-ORed data is encrypted based on the DES.

[0510] At step S76, the control section 306 of the recording and reproducing device cryptography process section 302 causes the encryption/decryption section 308 of the recording and reproducing device cryptography process section

302 to calculate the intermediate integrity check value. The intermediate value is calculated in accordance with the ICV calculation method described in Fig. 7 or the like.7 This is done using as a key the total-integrity-check-value-generating key Kicvt stored in the internal memory 307 of the recording and reproducing device cryptography process section 302 and using the integrity check values A and B and all the held content integrity check values as a message. Kicvt is stored in the internal memory 307. Kicvt incorporates the integrity check values A and B and all the held content integrity check values. The initial value may be IV=0 or the total-integrity-check-value-generating initial value IVt may be used ~~which is stored in the internal memory 307 of the recording and reproducing device cryptography process section 302.~~ Additionally, the intermediate integrity check value generated is stored in the recording and reproducing device cryptography process section 302 ~~of the recording and reproducing device 300 as required.~~

[0511] Then at step S77, the control section 301 of the recording and reproducing device 300 takes the localization field out from the usage policy (contained in the header section of the data read out from the external memory 402 of the recording device 400), to determine whether the downloaded content can be used only in this recording and reproducing device 300 (in this case, the localization field is set to 1), or also by other similar recording and reproducing devices 300 (in this case, the localization field is set to 0). If the result of the determination shows that the localization field is set to 1, that is, ~~it is set such that the downloaded content can be used only in this recording and reproducing device 300,~~ the process proceeds to step S80. A value of 1 means that it is set such that the downloaded content can be used only in this recording and reproducing device 300. If the localization is set to 0, ~~that is, it is set such that the content can also be used by other similar recording and reproducing device 300,~~ then the process proceeds to step S78. A value of 0 means that it is set such that the content can also be used by other similar recording and reproducing device

300. Step S77 may be processed by the cryptography process section 302.

[0512] At step S78, the total integrity check value ICVt is calculated in the same manner as step S58 described in "(7) Process for Downloading from Recording and Reproducing Device to Recording Device." That is, the control section 306 of the recording and reproducing device cryptography process section 302 causes the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 to calculate the total integrity check value ICVt. The total integrity check value ICVt is generated by using ~~as a key~~ a system signature key Ksys as a key to encrypt the intermediate integrity check value based on the DES, as shown in Fig. 25. Ksys can be stored in the internal memory 307 of the recording and reproducing device cryptography process section 302, ~~to encrypt the intermediate integrity check value based on the DES, as shown in the previously described Fig. 25.~~

[0513] The, the process proceeds to step S79 to compare the total integrity check value ICVt generated at step S78 with the ICVt in the header stored at step S71. If the values are equal, the process proceeds to step S82.

[0514] As previously described, the total integrity check value ICVt is used to verify that the integrity check values ICVa and ICVb and all the content block integrity check values have not been tampered with. Thus, if the total integrity check value generated by means of the above described process equals the integrity check value ICVt stored in the header, it is determined that the integrity check values ICVa and ICVb and all the content block integrity check values have not been tampered with in the data stored in the recording device 400.

[0515] If the result of the determination at step S77 shows that the localization field is set such that the downloaded content can be used only in this recording and reproducing device 300, that is, it is set to 1, the process proceeds to step S80.

[0516] At step S80, the control section 306 of the recording and reproducing device cryptography process section

302 causes the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 to calculate the integrity check value ICVdev unique to the recording and reproducing device 300. The integrity check value ICVdev unique to the recording and reproducing device 300 is generated, as shown in the previously described Fig. 25, by using ~~as a key a recording and reproducing device signature key Kdev as a key unique to the recording and reproducing device stored in the internal memory 307 of the recording and reproducing device cryptography process section 302,~~ to encrypt the intermediate integrity check value based on the DES, the intermediate integrity check value being held at step S58. Kdev is unique to the recording and reproducing device, and is stored in the internal memory 307. At step S81, the check value ICVdev (unique to the recording and reproducing device 300) calculated at step S80 is compared with the ICVdev stored at step S71, ~~and i~~ If they are equal, the process proceeds to step S82.

[0517] Thus, data signed with the same system signature key Ksys are successfully checked by a system (recording and reproducing device 300) having the same system signature key. ~~That is,~~ That is, such data have the same total integrity check value ICVt so as to be sharable. If, however, data ~~are is~~ signed with the recording and reproducing device signature key Kdev, ~~since this signature key is unique to the recording and reproducing device, the data signed with the recording and reproducing device signature key Kdev, that is,~~ the data stored in a recording device 400 after the signing cannot be reproduced if an attempt is made to reproduce them after this recording device 400 has been inserted in another recording and reproducing device 400. ~~That is,~~ That is, an error occurs due to a mismatch in the integrity check value ICVdev unique to the recording and reproducing device 300. Accordingly, the setting of the localization field enables contents to be arbitrarily set so as to be shared throughout the entire system or used only by particular recording and reproducing devices 300.

[0518] At step S82, the control section 301 of the recording and reproducing device 300 takes content block

information out from the block information table (BIT) (read out at step S74) and checks whether any content block is to be encrypted. If any content block is to be encrypted, the control section 301 reads this content block out from the external memory 402 of the recording device 400 via the recording device controller 303 of the recording and reproducing device 300. ~~and~~ It then transmits the content block to the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300. On receiving the content block, the control section 306 of the recording and reproducing device cryptography process section 302 causes the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 to decrypt the content. ~~while~~ The control section 306 also causes ~~ing~~ the encryption/decryption section 308 to calculate the content integrity check value at step S83, if the content block is to be verified.

[0519] Step S83 is similar to step S58 described in "(7) Process for Downloading from Recording and Reproducing Device to Recording Device." The control section 301 of the recording and reproducing device 300 takes content block information out from the block information table (BIT) and determines from the stored content integrity check value whether any content block is to be verified. If any content block is to be verified, the control section 301 receives this content block from the external memory 402 of the recording device 400 and transmits it to the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300. On receiving the content block, the control section 306 of the recording and reproducing device cryptography process section 302 causes the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 to calculate the content intermediate value.

[0520] The content intermediate value is generated by using the content key Kcon (decrypted at step S74) to decrypt the input content block in the DES CBC mode, separating the

resulting data into 8-byte pieces, and exclusive-ORing all these pieces.

[0521] Then, the control section 306 of the recording and reproducing device cryptography process section 302 causes the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 to calculate the content integrity check value. The content integrity check value is generated by using as a key the content-integrity-check-value-generating key Kicvc ~~stored in the internal memory 307 of the recording and reproducing device cryptography process section 302,~~ to encrypt the content intermediate value based on the DES. Kicvc is stored in the internal memory 307. Then, the control section 306 of the recording and reproducing device cryptography process section 302 compares this content integrity check value with the ICV in the content block received from the control section 301 of the recording and reproducing device 300 at step S71, and passes the result to the control section 301 of the recording and reproducing device 300. On receiving the result (and if the verification has been successful), the control section 301 of the recording and reproducing device 300 takes out the next content block to be verified. ~~and~~ It causes the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 to verify this content block. Similar verification processes are repeated until all the content blocks are verified. The initial value may be IV=0 or the content-integrity-check-value-generating initial value IVc may be used which is stored in the internal memory 307 of the recording and reproducing device cryptography process section 302. Additionally, all the checked content integrity check values are held in the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300. Furthermore, the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 monitors the order in which the content blocks are verified. This is done to consider the authentication to have failed if

the order is incorrect or if it is caused to verify the same content block twice or more.

[0522] The control section 301 of the recording and reproducing device 300 receives the result of the comparison of the content integrity check value. ~~(i~~ If no content block is to be verified, all the results of comparisons will be successful~~), and i~~ If the verification has been successful, it takes the decrypted content from the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300. It then takes out next content block to be verified and causes the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 to decrypt this content block. Similar verification processes are repeated until all the content blocks are decrypted.

[0523] At step S83, if the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 determines after the verification process that the content integrity check values are not equal, it considers the verification to have failed and avoids decrypting the remaining contents. In addition, the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 monitors the order in which the content blocks are decrypted. This is done to consider the decryption to have failed if the order is incorrect or if it is caused to decrypt the same content block twice or more.

[0524] If the verification of the integrity check value A has failed at step S72, if the verification of the integrity check value B has failed at step S75, if the verification of the total integrity check value ICVt has failed at step S79, if the verification of the integrity check value ICVdev unique to the recording and reproducing device 300 has failed at step S81, or if the verification of the content block content integrity check value has failed at step S81, then the process proceeds to step S84 to provide a predetermined error display because the verification is no good.

[0525] As described above, not only important data or content can be encrypted, concealed, or checked for tampering when the content is downloaded or used, ~~but~~ This can be done even if data on a recording medium are simply copied to another recording medium. ~~the~~ The content can be prevented from being correctly decrypted because the block information table key Kbit (for decrypting the block information table BIT) and the content key Kcon (for decrypting the content) are stored with the storage key Kstr unique to the recording medium. More specifically, ~~for example, at step S74 in Fig. 28, the~~ another recording device 400 cannot decrypt the data correctly because each recording device 400 decrypts data encrypted with a different storage key Kstr.

(9) Key Exchanging Process after Mutual Authentication

[0526] The data processing apparatus according to the present invention is partly characterized in that the recording device 400 can be used only after the above described mutual authentication process between the recording and reproducing device 300 and the recording device 400, and also in that the use form of the recording device is limited.

[0527] For example, to prevent a user from generating a recording device 400 such as a memory card, in which ~~a~~ content is stored by means of illegal copying or the like, and setting this recording device 400 in a recording and reproducing device 300 for use, the mutual authentication process is executed between the recording and reproducing device 300 and the recording device 400. ~~and (encrypted) e~~ Contents (that may be encrypted) can be transferred between the recording and reproducing device 300 and the recording device 400 only if they have been mutually authenticated.

[0528] To achieve the above restrictive process, according to the present data processing apparatus, all the processes in the cryptography process section 401 of the recording device 400 are executed based on preset command strings. That is, the recording device 400 has such a command process configuration that it sequentially obtains commands from a register based on command numbers. Fig. 29 is a view illustrating useful ~~in~~

~~explaining~~ the command process configuration of the recording device 400.

[0529] As shown in Fig. 29, between the recording and reproducing device 300 having the recording and reproducing device cryptography process section 302 and the recording device 400 having the recording device cryptography process section 401, command numbers (No.) are output from the recording device controller 303 to the communication section (including a reception register) 404 of the recording device 400 under the control of the control section 301 of the recording and reproducing device 300.

[0530] The recording device 400 has a command number managing section ~~2201~~-(2901?) in the control section 403 ~~in~~of the cryptography process section 401. The command number managing section 2901 holds a command register 2902. ~~to~~
Command register 2902 stores command strings corresponding to command numbers output from the recording and reproducing device 300. In the command strings, command numbers 0 to y are sequentially associated with execution commands, (as shown in the right of Fig. 29). The command number managing section 2901 monitors command numbers output from the recording and reproducing device 300 to take corresponding commands out from a command register 2902 for execution.

[0531] In command sequences stored in the command register 2902, a command string for an "authentication process sequence" is associated with the leading command numbers 0 to k, ~~as shown in the right of Fig. 29~~. Furthermore, command numbers p to s following the command string for the authentication process sequence are associated with a "decryption, key exchange, and encryption process command sequence 1," and the following command numbers u to y are associated with a "decryption, key exchange, and encryption process command sequence 2."

[0532] As previously described for the authentication process flow in Fig. 20, when the recording device 400 is installed in the recording and reproducing device 300, the control section 301 of the recording and reproducing device 300 transmits an initialization command to the recording

device 400 via the recording device controller 303. On receiving the command, the recording device 400 causes the control section 403 of the recording device cryptography process section 401 to receive the command via the communication section 404.—and— It then clears an authentication flag 2903. That is, an unauthenticated state is set. Alternatively, in such a case that power is supplied from the recording and reproducing device 300 to the recording device 400, the unauthenticated state ~~(?)~~—may be set ~~on~~upon power-on.

[0533] Then, the control section 301 of the recording and reproducing device 300 transmits an initialization command to the recording and reproducing device cryptography process section 302. At this point, it also transmits a recording device insertion port number. When the recording device insertion port number is transmitted, even if a plurality of recording devices 400 are connected to the recording and reproducing device 300, the recording and reproducing device 300 can simultaneously execute authentication with these recording devices 400 and transmit and receive data thereto and therefrom.

[0534] On receiving the initialization command, the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 causes the control section thereof to clear the authentication flag 2903₄ corresponding to the recording device insertion port number. That is, the unauthenticated state is set.

[0535] Once this initialization process has been completed, the control section 301 of the recording and reproducing device 300 sequentially outputs command numbers via the recording device controller 303. This is done in an ascending order starting with the command number 0. The command number managing section 2901 of the recording device 400 monitors the command numbers input from the recording and reproducing device 300 to ascertain that they are sequentially input starting with the command number 0.—and— It obtains the corresponding commands from the command register 2902 to execute various processes, such as the authentication process.

If the input command numbers are not in a specified order, an error occurs and a command number acceptance value is reset to an initial state.~~7~~~~t~~ That is, an executable command number is reset at 0.

[0536] In the command sequences stored in the command register 2902~~as shown in Fig. 29~~, the command numbers are imparted so as to carry out the authentication process first.~~7~~~~and f~~ Following this process sequence, ~~decryption~~the key exchange is decrypted, and an encryption process sequence is stored.

[0537] A specific example of ~~the decryption~~decrypting the key exchange~~7~~ and the encryption process sequence will be explained with reference to Figs. 30 and 31.

[0538] Fig. 30 shows part of the process executed in downloading a~~—~~content from the recording and reproducing device 300 to the recording device 400 as previously described in Fig. 22. Specifically, this process is executed between steps 59 and 60 in Fig. 22.

[0539] In Fig. 30, at step S3001, the recording device 400 receives data (ex. the block information table Kbit and the content key Kcon) encrypted with the session key Kses, from the recording and reproducing device 300. Thereafter, the command strings p to s (shown in the above described Fig. 29) are started. The command strings p to s are started after the authentication process commands 0 to k have been completed to cause authentication flags 2903~~and 2904~~ (shown in Fig. 29) to be set to indicate the completion. This is ensured by the command number managing section 2901 by accepting the command numbers only in the ascending order starting with 0.

[0540] At step S3002, the recording device stores ~~in the register~~the data (ex. the block information table Kbit and the content key Kcon) received from the recording and reproducing device 300 and encrypted with the session key Kses, in the register.

[0541] At step S3003, a process is executed which takes the data (ex. the block information table Kbit and the content key Kcon) encrypted with the session key Kses~~7~~ out from the register and decrypts them with the session key Kses.

[0542] At step S3004, a process is executed which encrypts the data (ex. the block information table Kbit and the content key Kcon) decrypted with the session key Kses, using the storage key Kstr.

[0543] The above process steps 3002 to 3004 correspond to processes included in the command numbers p to s in the command register previously described in Fig. 29. These processes are sequentially executed by the recording device cryptography process section 401 in accordance with the command numbers p to s received by the command number managing section 2901 of the recording device 400 from the recording and reproducing device 300.

[0544] At the next step S3005, the data (ex. the block information table Kbit and the content key Kcon), encrypted with the storage key Kstr, are stored in the external memory of the recording device. At this step, the recording and reproducing device 300 may read the data encrypted with the storage key Kstr, out from the recording device cryptography process section 401 and then stores them in the external memory 402 of the recording device 400.

[0545] The above described steps S3002 to S3004 constitute an uninterruptible, continuously-executed execution sequence. This is done even if, for example, the recording and reproducing device 300 issues a data read command at the end of the decryption process at step S3003. ~~Since this read command differs from the command numbers p to s set in the command register 2902 in the ascending order, the command number managing section 2901 does not accept execution of the read command.~~ Accordingly, the decrypted data resulting from the key exchange in the recording device 400 cannot be read out by an external device, for example, the recording and reproducing device 300, thereby preventing key data or contents from being illegally read out.

[0546] Fig. 31 shows part of the content reproducing process, previously described in Fig. 28, in which ~~a~~ content is read out from the recording device 400 and reproduced by the recording and reproducing device 300. Specifically, this process is executed at step S73 ~~in~~ of Fig. 28.

[0547] In Fig. 31, at step S3101, the data (ex. the block information table Kbit and the content key Kcon), encrypted with the storage key Kstr, are read out from the external memory 402 of the recording device 400.

[0548] At step S3102, the data (ex. the block information table Kbit and the content key Kcon), read out from the memory of the recording device 400 and encrypted with the storage key Kstr, are stored in the register. At this step, the recording and reproducing device 300 may read the data encrypted with the storage key Kstr, out from the external memory 402 of the recording device 400 and then store them in the register of the recording device 400.

[0549] At step S3103, the data (ex. the block information table Kbit and the content key Kcon), encrypted with the storage key Kstr, are taken out from the register and decrypted with the storage key Kstr.

[0550] At step S3104, the data (ex. the block information table Kbit and the content key Kcon), decrypted with the storage key Kstr, are encrypted with the session key Kses.

[0551] The above process steps 3102 to 3104 correspond to processes included in the command numbers u to y in the command register previously described in Fig. 29. These processes are sequentially executed by the recording device cryptography process section 406 in accordance with the command numbers u to y received by the command number managing section 2901 of the recording device from the recording and reproducing device 300.

[0552] At the next step S3105, the data (ex. the block information table Kbit and the content key Kcon) encrypted with the session key Kses are transmitted from the recording device 400 to the recording and reproducing device 300.

[0553] The above described steps S3102 to S3104 constitute an uninterruptible continuously-executed execution sequence. This is done even if, for example, the recording and reproducing device 300 issues a data read command at the end of the decryption process at step S3103. Since this read command differs from the command numbers u to y set in the command register 2902 in the ascending order, the command

number managing section 2901 does not accept execution of the read command. Accordingly, the decrypted data resulting from the key exchange in the recording device 400 cannot be read out by an external device, for example, the recording and reproducing device 300, thereby preventing key data or contents from being illegally read out.

[0554] For the process shown in Figs. 30 and 31, the example is shown where the block information table key Kbit and the content key Kcon are decrypted and encrypted by means of key exchange, ~~but~~ These command sequences, stored in the command register 2902 (shown in Fig. 29), may include decryption and encryption processes involving key exchanges for the content itself. The object to be decrypted or encrypted by means of key exchanges is not limited to the above-described example.

[0555] The key exchange process after the mutual authentication in the present data processing apparatus has been described. Thus, the key exchange process in the present data processing apparatus can be carried out only after the authentication process between the recording and reproducing device 300 and the recording device 400 has been completed. Further, decrypted data can be prevented from being externally accessed during the key exchange process, thereby ensuring the improved security of contents and key data.

(10) Plural Content Data Formats and Download and Reproduction Processes Corresponding to Each Format

[0556] In the above-described embodiment, for example, the data format for the medium 500 or communication means 600 shown in Fig. 3 is of the type shown in Fig. 4. The data format for the medium 500 or the communication means 600 is not limited to the one shown in Fig. 4, but preferably depends on the content, ~~that is, whether the content is~~ (e.g., music, image data, a program such as a game, or the like). A plurality of data formats as well as processes for downloading and reproducing data from and to the recording device 400 will be explained.

[0557] Figs. 32 to 35 show four different data formats. A data format used on the medium 500 or the communication means 600 (shown in Fig. 3) is shown in the left of each figure, while a data format used in storing data in the external memory 402 of the recording device 400 is shown in the right of each figure. An outline of the data formats shown in Figs. 32 to 35 will first be provided, and the contents of each data in each format and differences among data in each format will be explained.

[0558] Fig. 32 shows a format type 0, which is of the same type as that shown as an example in the above description. The format type 0 is characterized in that the entire data ~~are~~is divided into N data blocks each having an arbitrary size. ~~That is, blocks 1 to N, each of which is arbitrarily encrypted so that data can be configured by mixing together encrypted blocks and non-encrypted blocks, that is, (i.e., plain text blocks).~~ The blocks are encrypted with the content key Kcon, which is encrypted with the distribution key Kdis on the medium 500 or with the storage key Kstr stored in the internal memory 405 of the recording device 400 when it is stored in the recording device 400. The block information key Kbit is also encrypted with the distribution key Kdis on the medium 500 or with the storage key Kstr stored in the internal memory 405 of the recording device 400 when it is stored in the recording device 400. These key exchanges are carried out in accordance with the process described in "(9) Key Exchange Process after Mutual Authentication."

[0559] Fig. 33 shows a format type 1, in which the entire data ~~are~~is divided into N data blocks. ~~That is, blocks 1 to N, as in the format type 0,~~ but which differs from the format type 0 in that the N blocks are all of the same size. The aspect of the process for encrypting blocks with the content key Kcon is similar to that in the format type 0. Additionally, as in the above described format type 0, the content key Kcon and the block information table key Kbit are encrypted with the distribution key Kdis on the medium 500 or with the storage key Kstr stored in the internal memory 405 of the recording device 400 when it is stored in the recording device

400. Unlike the format type 0, the format type 1 has a fixed block configuration to simplify configuration data such as data length for each block, thereby enabling a memory size for block information to be reduced compared to the format type 0.

[0560] In the example ~~of configuration~~shown in Fig. 33, each block comprises a set of an encrypted part and a non-encrypted (plain text) part. If the length and configuration of the block are thus regular, each block length or configuration need not be checked during the decryption process or the like, thereby enabling efficient decryption and encryption processes. In the format 1, the parts constituting each block, ~~that is,~~ the encrypted part and the non-encrypted (plain text) part, can each be defined as an object to be checked, so that the content integrity check value ICVi is defined for a block containing a part that must be checked.

[0561] Fig. 34 shows a format type 2.~~7~~ Format type 2 which is characterized in that the data ~~are~~is divided into N data blocks all having the same size.~~7~~ ~~that is,~~ b Blocks 1 to N, ~~are each of which is~~ encrypted with an individual block key Kblc. Each block key Kblc is encrypted with the content key Kcon.~~7~~ ~~which~~ Kcon is encrypted with the distribution key Kdis on the medium 500 or with the storage key Kstr stored in the internal memory 405 of the recording device 400 when it is stored in the recording device 400. The block information table key Kbit is also encrypted with the distribution key Kdis on the medium or with the storage key Kstr stored in the internal memory of the recording device when it is stored in the recording device.

[0562] Fig. 35 shows a format type 3.~~7~~ Format type 3 is characterized in that the data ~~are~~is divided into N data blocks all having the same size.~~7~~ ~~that is,~~ b Blocks 1 to N, ~~are each of which is~~ encrypted with an individual block key Kblc, as in the format type 2.~~7~~ ~~and in that e~~ Each block key Kblc is encrypted with the distribution key Kdis on the medium 500 or with the storage key Kstr on the recording device 400, without the use of the content key. No content key Kcon is present on the medium 500 or on the device 400. The block information table key Kbit is encrypted with the distribution

key Kdis on the medium 500 or with the storage key Kstr stored in the internal memory 405 of the recording device 400 when it is stored in the recording device 400.

[0563] Next, the contents of the data in the above format types 0 to 3 will be described. As previously described, the data are roughly divided into two sections, ~~that is namely~~, the header section and the content section. The header section contains the content ID, the usage policy, the integrity check values A and B, the total integrity check value, the block information table key, the content key, and the block information table.

[0564] The usage policy stores the data length of a ~~content~~, its header length, its format type (formats 0 to 3 described below), and content type indicating whether the content is a program or data. ~~It also stores a localization flag.~~ The localization flag determines whether the content can be used only by a particular recording and reproducing device 300 (as described in the section relating to the processes for downloading and reproducing a content to and from the recording device 400). ~~a~~ The usage policy also stores a permission flag for a content copying or moving process, and various localization and process information for the content (such as a content encryption algorithm and a mode).

[0565] The integrity check value A, ~~ICVa~~, is used to check the content ID and the usage policy. ~~and ICVa is generated using, for example, the method described in the above-~~ described Fig. 23.

[0566] The block information table key Kbit is used to encrypt a block information table. ~~and~~ It is encrypted with the distribution key Kdis on the medium 500 or with the storage key Kstr stored in the internal memory 405 of the recording device 400 when it is stored in the recording device 400, as previously described.

[0567] The content key Kcon is used to encrypt ~~a~~ content. For the format types 0 and 1, it is encrypted with the distribution key Kdis on the medium 500 or with the storage key Kstr stored in the internal memory 405 of the recording device 400 when it is stored in the recording device 400,

similarly to the block information table key Kbit. For the format type 2, the content key Kcon is also used to encrypt the block key Kblc configured for each content block. Additionally, for the format type 3, no content key Kcon is present.

[0568] The block information table describes information on the individual blocks and stores the size of each block and a flag indicating whether the block has been encrypted. ~~That is, the block information table stores information indicating whether or not the block is to be checked (ICV).~~ If the block is to be checked, the block integrity check value ICVi (the integrity check value for the block i) is defined and stored in the table. This block information table is encrypted with the block information table key Kbit.

[0569] If the block has been encrypted, the block integrity check value, ~~that is,~~ (the content integrity check value ICVi) is generated by exclusive-ORing the entire plain text (decrypted text) every 8 bytes, and then encrypting the obtained value with the content-integrity-check-value-generating key Kicvc stored in the internal memory 307 ~~of the recording and reproducing device 300.~~ Additionally, if the block has not been encrypted, the block integrity check value is generated by sequentially inputting the entire block data (plain text) to a tamper-check-value-generating function shown in Fig. 36 (DES-CBC-MAC using the content-integrity-check-value-generating key Kicvc) in such a manner that 8 bytes are input each time. Fig. 36 shows an example of a configuration for generating the content block integrity check value ICVi. Each message M constitutes ~~each~~ a set of 8 bytes of decrypted text data or plain text data.

[0570] For the format type 1, if at least one of the parts in the block is data to be processed with the integrity check value ICVi, (that is, a part to be checked), the content integrity check value ICVi is defined for that block. An integrity check value P-ICVij (for a part j of a block ~~±I~~) is generated by exclusive ORing the entire plain text (decrypted text) every 8 bytes and then encrypting the obtained data with the content-integrity-check-value-generating value Kicvc. In

addition, if a part j has not been encrypted, the integrity check value $P-ICV_{ij}$ is generated by sequentially inputting the entire block data (plain text) to the tamper-check-value-generating function shown in Fig. 36 (DES-CBC-MAC using the content-integrity-check-value-generating key K_{icvc}) in such a manner that 8 bytes are input each time.

[0571] Further, if the block i contains one part having [ICV flag = subject of ICV] indicating that it is to be checked, the integrity check value $P-ICV_{ij}$ generated using the above method is directly used as the block integrity check value ICV_i . If the block i contains a plurality of parts having [ICV flag = subject of ICV] indicating that they are to be checked, the integrity check value $P-ICV_{ij}$ is generated by connecting a plurality of parts integrity check values $P-ICV_{ij}$ together in accordance with part numbers to obtain data and sequentially inputting the entire data (plain data) to the tamper-check-value-generating function shown in Fig. 37 (DES-CBC-MAC using the content-integrity-check-value-generating key K_{icvc}) in such a manner that 8 bytes are input each time. Fig. 37 shows an example of configuration for generating the content block content integrity check value ICV_i .

[0572] The block integrity check value ICV_i is not defined for the format types 2 or 3.

[0573] The integrity check value $B_{\underline{\quad}} \div ICV_{b_{\underline{\quad}}}$ is used to check the block information table key, the content key, and the entire block information table. ~~and It is generated using, for example, the method described in the previously described Fig. 24.~~

[0574] The total integrity check value, ICV_t , is used to check the entirety of the previously described ~~integrity check values A \div ICV $_a$ and B \div ICV $_b$~~ , and the integrity check value ICV_i contained in each block of the content to be checked. ~~and ICV $_t$ is generated by applying the system signature key K_{sys} to the intermediate integrity check value generated from each integrity check value, such as the integrity check value A \div ICV $_a$, to execute the encryption process as described in the previously described Fig. 25.~~

[0575] For the format types 2 and 3, the total integrity check value ICVt is generated by applying the system signature key Ksys to the intermediate integrity check value generated by connecting the previously described integrity check values A÷ICVa and B÷ICVb to the content data, ~~that is,~~ (the entire content data between the block key in block 1 and the final block), to execute the encryption process. Fig. 38 shows an example of a configuration for generating the total integrity check value ICVt for the format types 2 and 3.

[0576] The unique integrity check value ICVdev is substituted with the total integrity check value ICVt if the previously described localization flag is set to 1, ~~that is,~~ That is, it indicates that the content can be used only by a particular recording and reproducing device. For the format types 0 and 1, the unique integrity check value ICVdev is generated to check the previously described integrity check values A÷ICVa and B÷ICVb and the integrity check value ICVi contained in each block of the content to be checked. Specifically, the unique integrity check value ICVdev is generated by applying the recording and reproducing device signature key Kdev to the intermediate integrity check value generated from the integrity check values such as the integrity check value A÷ICVa, as explained in the description of previously described Fig. 25 or 38.

[0577] Next, processes for downloading ~~a~~ content of each of the format types 0 to 3 from the recording and reproducing device 300 to the recording device 400, and processes executed by the recording and reproducing device 300 to reproduce a content of each of the format types 0 to 3 from the recording device 400, will be described with reference to the flow charts in Figs. 39 to 44.

[0578] First, the process for downloading ~~a~~ content of the format type 0 or 1 will be explained with reference to Fig. 39.

[0579] The process shown in Fig. 39 is started, for example, by installing the recording device 400 into the recording and reproducing device ~~300 shown in Fig. 3.~~ At step S101, authentication is executed between the recording and reproducing device 300 and the recording device 400, and this

step is carried out in accordance with the authentication process flow previously described in Fig. 20.

[0580] If the authentication process at step S101 has been completed to set the authentication flag, then at step S-102, the recording and reproducing device 300 reads data of a predetermined format from the medium 500 via the read section 304, the medium 500 storing content data, or uses the communication section 305 to receive data from the communication means 600 in accordance with a predetermined format. Then, the control section 301 of the recording and reproducing device 300 transmits the header section of the data to the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300.

[0581] Next, at step S103, the control section 306 of the recording and reproducing device cryptography process section 302 causes the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 to calculate the integrity check value A. The integrity check value A is calculated in accordance with the ICV calculation method described in Fig. 7. ~~using~~ It uses as a key the integrity-check-value-A-generating key Kicva stored in the internal memory 307 of the recording and reproducing device cryptography process section 302. ~~and using~~ It uses the content ID and the usage policy as a message, as shown in Fig. 23. Then at step S104, the integrity check value A and the check value+ ICVa stored in the header are compared together. ~~and i~~ If they are equal, the process proceeds to step S105.

[0582] As previously described, the check value A, ICVa is used to verify that the content ID and the usage policy have not been tampered with. If the integrity check value A calculated, for example, in accordance with the ICV calculation, (using as a key the integrity-check-value-A-generating key Kicva stored in the internal memory 307 of the recording and reproducing device cryptography process section 302 and using the content ID and the usage policy as a message), equals the check value+ ICVa stored in the header, it

is determined that the content ID and the usage policy have not been tampered with.

[0583] Next, at step S105, the control section 306 of the recording and reproducing device cryptography process section 302 causes the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 to obtain or generate the distribution key Kdis. The distribution key Kdis is generated using, for example, the master key MKdis for the distribution key, as in step S53 in the previously described Fig. 22.

[0584] Then at step S106, the control section 306 of the recording and reproducing device cryptography process section 302 uses the encryption/decryption section 308 ~~of the recording and reproducing device cryptography process section 302~~ as well as the generated distribution key Kdis, to decrypt the block information table key Kbit and content key Kcon stored in the header section of the data obtained from the medium 500 via the read section 304 or received from the communication means 600 via the communication section 305.

[0585] Further, at step S107, the control section 306 of the recording and reproducing device cryptography process section 302 uses the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 to decrypt the block information table with the decrypted block information table key Kbit.

[0586] Further, at step S108, the control section 306 of the recording and reproducing device cryptography process section 302 calculates the integrity check value B (ICVb') from the block information table key Kbit, the content key Kcon, and the block information table (BIT). The integrity check value B is generated, as shown in Fig. 24, ~~by using as a key the integrity check value B-generating key Kicvb stored in the internal memory 307 of the recording and reproducing device cryptography process section 302,~~ to decrypt an exclusive-ORed value based on the DES. This is done by using the integrity-check-value-B-generating key Kicvb stored in the internal memory 307. ~~‡The exclusive-ORed value comprises~~ the block information table key Kbit, the content key Kcon,

and the block information table (BIT). Then at step S109, the ~~integrity check value BICVb'~~ and the ICVb in the header are compared together, and if they are equal, the process proceeds to step S110.

[0587] As previously described, the check value B, ICVb, is used to verify that the block information table key Kbit, the content key Kcon, and the block information table have not been tampered with. If the integrity check value B ICVb' generated by using as a key the integrity check value B-generating key Kicvb stored in the internal memory 307 of the recording and reproducing device cryptography process section 302, ~~dividing the block information table key Kbit, the content key Kcon, and the block information table (BIT) into 8-byte pieces, exclusive-Oring these data, and encrypting the exclusive-Oring data based on the DES,~~ equals the check value ICVb stored in the header, it is determined that the block information table key Kbit, the content key Kcon, and the block information table have not been tampered with. As described earlier, ICVb' is generated by using the integrity-check-value-B-generating key Kicvb; dividing the block information table key Kbit, the content key Kcon, and the block information table (BIT) into 8-byte pieces; exclusive-Oring these data; and encrypting the exclusive-Oring data based on the DES.

[0588] At step S110, the control section 306 of the recording and reproducing device cryptography process section 302 causes the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 to calculate the intermediate integrity check value. The intermediate value is calculated in accordance with the ICV calculation method described in Fig. 7 or the like. This is done using as a key the total-integrity-check-value-generating key Kicvt as a key stored in the internal memory 307 of the recording and reproducing device cryptography process section 302 and using the integrity check values A and B and all the held content integrity check values as a message. Kicvt is stored in the internal memory 307. The intermediate integrity check value generated is stored in the recording and

reproducing device cryptography process section 302 of the recording and reproducing device 300, as required.

[0589] Next, at step S111, the control section 306 of the recording and reproducing device cryptography process section 302 causes the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 to calculate the total integrity check value ICvt'. As shown in Fig. 25, the total integrity check value ICvt is generated by using ~~as a key~~ a system signature key Ksys as a key stored in the internal memory 307 of the recording and reproducing device cryptography process section 302, to encrypt the intermediate integrity check value based on the DES. Ksys is stored in the internal memory. Then at step S112, the total integrity check value ICvt generated and the ICvt' in the header stored at step S112 are compared together, and if they are equal, the process proceeds to step S113.

[0590] As previously described in Fig. 4, the total integrity check value ICvt is used to verify that all of the integrity check values ICVa and ICVb and the integrity check value for each content block have not been tampered with. Thus, if the total integrity check value generated by means of the above described process equals the integrity check value ICvt stored in the Hheader, it is determined that all of the integrity check values ICVa and ICVb and the integrity check value for each content block have not been tampered with.

[0591] Then at step S113, the control section 301 of the recording and reproducing device 300 ~~takes~~ content block information out from the block information table (BIT) and checks whether any content block is to be verified. If any content block is to be verified, the content integrity check value has been stored in the block information in the header.

[0592] If any content block is to be verified, then at step S114, the control section 301 reads this content block out from the medium 500 (using the read section 304 of the recording and reproducing device 300) or receives it from the communicating means 600 (by using the communication section 305 of the recording and reproducing device 300), and transmits the content block to the recording and reproducing

device cryptography process section 302 of the recording and reproducing device 300. On receiving the content block, the control section 306 of the recording and reproducing device cryptography process section 302 causes the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 to calculate the content integrity check value ICVi'.

[0593] If the block has been encrypted, the content integrity check value ICVi is generated by decrypting the input content block in the DES CBC mode using the content key Kcon,— Then it exclusive-ORs~~ing~~ all of the decrypted text every 8 bytes.—a And then it encrypts~~ing~~ the generated content intermediate value with the content-integrity-check-value-generating key Kicvc stored in the internal memory 307 of the recording and reproducing device 300. Additionally, if the block has not been encrypted, the content integrity check value is generated by sequentially inputting the entire block data (plain text) to the tamper-check-value-generating function shown in Fig. 36 (DES-CBC-MAC using the content-integrity-check-value-generating key Kicvc) in such a manner that 8 bytes are input each time.

[0594] Then at step S115, the control section 306 of the recording and reproducing device cryptography process section 302 compares this content integrity check value with the ICV in the content block received from the control section 301 of the recording and reproducing device 300 at step S102.—a And it passes the result to the control section 301 of the recording and reproducing device 300. On receiving the result (and if the verification has been successful), the control section 301 of the recording and reproducing device 300 takes out the next content block to be verified and causes the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 to verify this content block. Similar verification processes are repeated until all the content blocks are verified (step S116).

[0595] In this regard, if the check values are not equal at any of steps 104, 109, 112, and 115, an error occurs to end the download process.

[0596] Then at step S117, the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 causes the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 to encrypt the block information key Kbit and content key Kcon decrypted at step S106.~~—~~ This is performed using the session key Kses made sharable during the mutual authentication. The control section 301 of the recording and reproducing device 300 reads the block information table key Kbit and the content key Kcon out from the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 and then transmits them to the recording device 400 via the recording device controller 303 of the recording and reproducing device 300.

[0597] Then at step S118,~~—on receiving the block information table key Kbit and the content key Kcon transmitted from the recording and reproducing device 300,~~ the recording device 400 causes the encryption/decryption section 406 of the recording device cryptography process section 401 to decrypt the received data with the session key Kses (made sharable during the mutual authentication). Step 118 is performed upon receiving the block information table key Kbit and the content key Kcon that is transmitted from the recording and reproducing device 300.~~—and to then reencrypt t~~
The decrypted data in then reencrypted using the storage key Kstr, which is unique to the recording device which is stored in the internal memory 405 of the recording device cryptography process 401. Then, the control section 301 of the recording and reproducing device 300 reads the block information key Kbit and the content key Kcon out from the recording device 400 via the recording device controller 303 of the recording and reproducing device 300.~~—t~~ The block information key Kbit and the content key Kcon can being reencrypted with the storage key Kstr. That is, the block information table key Kbit encrypted with the distribution key Kdis is exchanged with the content key Kcon.

[0598] Then at step S119, the control section 301 of the recording and reproducing device 300 takes the localization field out from the usage policy in the header section of the data. ~~7~~ This is done to determine whether the downloaded content can be used only in this recording and reproducing device 300. If the localization field is set to 1, the downloaded content can be used only by the recording and reproducing device 300. ~~7~~ If the localization field is set to 0, the downloaded content can also be used by other similar recording and reproducing devices 300. If the result of the determination shows that the localization field is set to 1, the process proceeds to step S120.

[0599] At step S120, the control section 301 of the recording and reproducing device 300 causes the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 to calculate the integrity check value unique to the recording and reproducing device 300. The integrity check value unique to the recording and reproducing device 300 is generated by using as a key a recording and reproducing device signature key Kdev stored in the internal memory 307 of the recording and reproducing device cryptography process section 302. ~~7~~ This is performed to encrypt the intermediate integrity check value based on the DES. ~~7~~ The intermediate integrity check value can be generated at step S110. The calculated integrity check value ICVdev unique to the recording and reproducing device 300 substitutes for the total integrity check value ICVt.

[0600] As previously described, the system signature key Ksys is used to add a common signature or ICV to the distribution system. ~~7~~ and ~~t~~ The recording and reproducing device signature key Kdev varies depending on the recording and reproducing device 300 and is used by the recording and reproducing device 300 to add a signature or ICV. That is, data signed with the system signature key Ksys are successfully checked by a system (recording and reproducing device 300) having the same system signature key. ~~7~~ that is, In other words, such data have the same total integrity check value ICVt so as to be sharable. If, however, data are signed

with the recording and reproducing device signature key K_{dev} , (since this signature key is unique to the recording and reproducing device), ~~the data signed with the recording and reproducing device signature key K_{dev} , that is,~~ the data stored in a recording device after the signing cannot be reproduced if an attempt is made to reproduce them after this recording device 400 has been inserted in another recording and reproducing device 300; ~~that is,~~ In other words, an error occurs due to the unequal integrity check values ICV_{dev} unique to the recording and reproducing device 300. In the data processing apparatus according to the present invention, the setting of the localization field enables contents to be arbitrarily set so as to be shared throughout the entire system or used only by particular recording and reproducing devices 300.

[0601] Next, at step S121, the control section 301 of the recording and reproducing device 300 causes the recording and reproducing device cryptography process section 302 to form a storage data format. As previously described, one of the three format types, 0 to 3, is set in the usage policy (see Fig. 5) in the header. This is done so that data are formed in accordance with the storage format ~~in the right~~ of one of the previously described Figs. 32 to 35 depending on the set type. The flow shown in Fig. 39 is for the format 0 or 1, so that the data are formed into one of the formats in Figs. 32 and 33. Once the storage data format has been completed at step S121, the control section 301 of the recording and reproducing device 300 stores the content in the external memory 402 of the recording device 400 at step S122.

[0602] How the process for downloading content data of the format type 0 or 1 is carried out has been described.

[0603] The process for downloading content data of the format type 2 will be explained with reference to Fig. 40. Differences from the above described process for downloading data of the format type 0 or 1 will be focused on.

[0604] Steps S101 to S109 are similar to the above described process for downloading data of the format type 0 or 1, so description thereof is omitted.

[0605] Since the format type 2 has no content integrity check value ICVi defined therefor as previously described, the block information table contains no content integrity check value ICVi. The intermediate integrity check value in the format type 2 is generated by applying the system signature key Ksys to the intermediate integrity check value (generated by connecting the integrity check values A and B to the entire content data between the leading data of the first block (the block key in the block 1) and the final block), to execute the encryption process.

[0606] Thus, in the process for downloading data of the format type 2, the content data ~~are~~is read out at step S151.~~7~~ ~~and~~ ~~the~~ The intermediate integrity check value is generated based on the integrity check values A and B and the read-out content data at step S152. In this regard, the content data ~~are~~is not decrypted even if ~~they~~it ~~has~~ve been encrypted.

[0607] For the format type 2, the processes for decrypting the block data and collating the content integrity check values are omitted, contrary to the previously described process for the format type 0 or 1, thereby increasing the processing speed.

[0608] The processing at step S111 and subsequent steps is similar to that for the format type 0 or 1, so description thereof is omitted.

[0609] How the process for downloading content data of the format type 2 is carried out has been described. As described above, the process for downloading data of the format type 2 omits the processes for decrypting the block data and collating the content integrity check values contrary to the process for the format type 0 or 1, thereby increasing the processing speed.~~7~~ ~~the~~ This format is thus suitable for processing of music data or the like which must be executed in real time.

[0610] Next, the process for downloading content data of format type 3 will be described with reference to Fig. 41. The following description will focus on differences from the above described download process for the format types 0, 1, and 2.

[0611] Steps S101 to S105 are similar to those of the above described download process for the format types 0, 1, and 2, so description thereof is omitted.

[0612] The process for the format type 3 essentially has many characteristics in common with that for the format type 2, but differs therefrom in that the format type 3 has no content key in that the block key Kblc is stored in the recording device 400 after encryption with the storage key Kstr.

[0613] The following description will focus on the differences between the download process for the format type 3 and that for the format type 2. With the format type 3, at step S161, (which followsing step S105), the block information table key is decrypted. The control section 306 of the recording and reproducing device cryptography process section 302 uses the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302, as well as the distribution key Kdis generated at step S105, to decrypt the block information table key Kbit. Kbit is stored in the header section of the data obtained from the medium 500 via the read section 304, or received from the communication means 600 via the communication section 305. With the format type 3, data contains no content key Kcon, so that the process for decrypting the content key Kcon is not executed.

[0614] At the next step S107, the block information table key Kbit (decrypted at step S161) is used to decrypt the block information table. ~~and at step S162, the control section 306 of the recording and reproducing device cryptography process section 302 generates integrity check value B(ICVb') from the block information table key Kbit and block information table (BIT). The integrity check value B is generated by using as a key the integrity-check-value-B-generating key Kicvb, stored in the internal memory 307 of the recording and reproducing device cryptography process section 302.~~ This is performed to encrypt the exclusive-ORed value comprising the block information table key Kbit and block information table (BIT), based on the DES. Kicvb is stored in the internal memory 307. Next, at step S109, the integrity

check value B (ICVb) and the ICVb in the header are compared together. ~~and if~~ If they are equal, the process proceeds to step S151.

[0615] With the format type 3, the check value B, ICVb functions to verify that the block information table key Kbit and the block information table have not been tampered with. If the integrity check value B generated equals the check value ICVb stored in the header, it is determined that the block information table key Kbit and the block information table have not been tampered with.

[0616] Steps S151 to S112 are similar to those of the process for the format type 2, and description thereof is omitted.

[0617] At step S163, the block key Kblc, contained in the content data read out at step S151, is decrypted with the distribution key Kdis generated at step S105.

[0618] Then at step S164, the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 causes the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 to encrypt the block information key Kbit (decrypted at step S161) and the block key Kblock (decrypted at step S163), using the session key Kses made sharable during the mutual authentication. The control section 301 of the recording and reproducing device 300 reads the block information table key Kbit and the block key Kblc out from the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 and then transmits ~~these~~ this data to the recording device 400 via the recording device controller 303 of the recording and reproducing device 300.

[0619] Then at step S165, ~~on receiving the block information table key Kbit and the block key Kblc transmitted from the recording and reproducing device 300,~~ the recording device 400 causes the encryption/decryption section 406 of the recording device cryptography process section 401 to decrypt the received data with the session key Kses. Step 165 occurs upon receiving the block information table key Kbit and the

block key Kblc that are transmitted from the recording and reproducing device 300. Kses was made sharable during the mutual authentication. and to then reencrypt The decrypted data is then reencrypted using the storage key Kstr which is unique to the recording device 400 which is stored in the internal memory 405 of the recording device cryptography process 401. The control section 301 of the recording and reproducing device 300 reads the block information table key Kbit and the block key Kblc reencrypted by a storage key Kstr from the recording device 400 via the recording device controller of the recording and reproducing device 300. That is, the block information table key Kbit and block key Kblc initially encrypted with the distribution key Kdis are replaced with the block information table key Kbit and block key Kblc reencrypted with the storage key Kstr.

[0620] The subsequent steps S119 to S122 are similar to those for the format types 0, 1, and 2, so description thereof is omitted.

[0621] The aspect of the process for downloading content data of the format type 3 has been described. As described above, the download process for the format type 3 omits the decryption of the block data and the process for collating the content integrity check value as for the format type 2, thereby enabling prompt processing. ~~+/t~~ The format type 3 is thus suitable for processing data such as music data, which requires ~~real-time~~ time processing. In addition, since the range within which the encrypted content is protected is localized by the block key Kblc, advanced security is achieved compared to the format type 2.

[0622] Next, processes for reproducing data of each of the format types 0 to 3 from the recording device 400 ~~of the recording and reproducing device 300~~ will be explained with reference to the flow charts in Figs. 42 to 45.

[0623] First, a process for reproducing ~~a~~ content of the format type 0 will be explained with reference to Fig. 42.

[0624] Step S201 corresponds to an authentication process between the recording and reproducing device 300 and the recording device ~~and 400~~. It is executed in accordance with

the authentication process flow previously described in Fig. 20.

[0625] Once the authentication process at step S201 has been completed to set the authentication flag, ~~at step S202,~~ the recording and reproducing device 300, at step S202, reads the header of data of a predetermined format out from the recording device 400 and transmits it to the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300.

[0626] Then at step S203, the control section 306 of the recording and reproducing device cryptography process section 302 causes the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 to calculate the integrity check value A. The integrity check value A, IVCa', is calculated using as a key the integrity-check-value-A-generating key Kicva stored in the internal memory 307 of the recording and reproducing device cryptography process section 302 and using the content ID and the usage policy as a message, as shown in the previously described Fig. 23. Then, the integrity check value A, IVCa', and the check value÷ ICVa stored in the header are compared together at step S204. ~~and if~~ If they are equal, the process proceeds to step S205.

[0627] The check value A, ICVa, is used to verify that the content ID and the usage policy have not been tampered with. If the calculated integrity check value A, IVCa', equals the check value÷ ICVa stored in the header, it is determined that the content ID and the usage policy have not been tampered with.

[0628] Then at step S205, the control section 301 of the recording and reproducing device 300 takes out, from the read-out header section, the block information table key Kbit and content key Kcon (encrypted with the storage key Kstr unique to the recording device) and then transmits them to the recording device 400 via the recording device controller 303 of the recording and reproducing device 300.

[0629] On receiving the block information table key Kbit and the content key Kcon (transmitted from the recording and

reproducing device 300), the recording device 400 causes the encryption/decryption section 406 of the recording device cryptography process section 401 to decrypt the received data with the storage key Kstr (unique to the recording device which is stored in the internal memory 405 of the recording device cryptography process) and to then reencrypt the decrypted data using the session key Kses (made sharable during the mutual authentication). This process is as previously described in detail in (9) Key Exchange Process after Mutual Authentication.

[0630] At step S206, the control section 301 of the recording and reproducing device 300 receives the block information table key Kbit and content key Kcon reencrypted with the session key Kses, from the recording device 400, via the recording device controller 303 of the recording and reproducing device 300.

[0631] Then at step S207, the control section 301 of the recording and reproducing device 300 transmits the received block information table key Kbit and content key Kcon (which are reencrypted with the session key Kses), to the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300. On receiving the block information table key Kbit and content key Kcon reencrypted with the session key Kses the content block, the cryptography process section 302 of the recording and reproducing device 300 causes the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 to decrypt these keys Kbit and Kcon with the session key Kses (made sharable during the mutual authentication).

[0632] Further at step S208, the decrypted block information table key Kbit is used to decrypt the block information read out at step S202. The recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 replaces the decrypted block information table key Kbit, content key Kcon, and block information table BIT with the block information table key Kbit, content key Kcon, and block information table BIT contained in the header read out at step S202, to hold the

latter. Additionally, the control section 301 of the recording and reproducing device 300 reads the decrypted block information table BIT out from the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300.

[0633] Further, at step S209, the control section 306 of the recording and reproducing device cryptography process section 302 generates the integrity check value B(ICVb') from the block information table key Kbit, the content key Kcon, and the block information table (BIT). The integrity check value B is generated, as shown in Fig. 24, by using as a key the integrity-check-value-B-generating key Kicvb ~~stored in the internal memory 307 of the recording and reproducing device cryptography process section 302,~~ to decrypt the exclusive-ORED value comprising the block information table key Kbit, the content key Kcon, and the block information table (BIT), based on the DES. Kicvb is stored in the internal memory 307. Then at step S210, the integrity check value B, ICVb', and the ICVb in the header are compared together. ~~and if~~ If they are equal, the process proceeds to step S211.

[0634] The check value B, ICVb is used to verify that the block information table key Kbit, the content key Kcon, and the block information table have not been tampered with. If the integrity check value B generated equals the check value+ICVb stored in the header, it is determined that the block information table key Kbit, the content key Kcon, and the block information table stored in the recording device 400 have not been tampered with.

[0635] At step S211, the control section 306 of the recording and reproducing device cryptography process section 302 causes the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 to calculate the intermediate integrity check value. The intermediate value is calculated in accordance with the ICV calculation method described in Fig. 7, using ~~as a key~~ the total-integrity-check-value generating key Kicvt as a key. Kicvt is stored in the internal memory 307 of the recording and reproducing device cryptography process section 302. ~~and~~

~~using~~ ~~t~~ The integrity check values A and B in the verified header and all the content integrity check values in the block information table are used as a message, as shown in Fig. 25. In this regard, the intermediate integrity check value generated is stored in the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 as required.

[0636] Next, at step S212, the control section 301 of the recording and reproducing device 300 takes the localization field out from the usage policy ~~contained in the header section of the data read from the external memory 402 of the recording device 400~~ to determine whether the content to be reproduced can be used only by this recording and reproducing device 300 (in this case, the localization field is set to 1) or also by other similar recording and reproducing devices 300 (in this case, the localization field is set to 0). The usage policy is contained in the header section of the data read from the external memory 402 of the recording device 400. If the result of the determination shows that the localization field is set to 1, that is, the reproduced content can be used only by this recording and reproducing device 300, the process proceeds to step S213. If the localization field is set to 0, that is, the reproduced content can also be used by other similar recording and reproducing devices 300, the process proceeds to step S215. The processing at step S211 may be executed by the cryptography process section 302.

[0637] At step S213, the control section 301 of the recording and reproducing device 300 causes the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 to calculate the integrity check value ICVdev'. ICVdev' is unique to the recording and reproducing device 300. The integrity check value ICVdev', unique to the recording and reproducing device, is generated, as shown in Fig. 25, by using ~~as a key~~ a recording and reproducing device signature key Kdev ~~as a key stored in the internal memory 307 of the recording and reproducing device cryptography process section 302,~~ to decrypt the intermediate integrity check value based on the

DES. ~~_____~~ ~~The intermediate integrity check value being~~ can be
held at step S58. Kdev is stored in the internal memory 307.

[0638] Then at step S214, the integrity check value ICVdev' (unique to the recording and reproducing device 300) calculated at step S213, and the ICVdev in the header read out at step S202, are compared together. ~~_____~~ ~~and i~~ If they are equal, the process proceeds to step S217.

[0639] ~~On the other hand, a~~ At step S215, the control section 306 of the recording and reproducing device cryptography process section 302 causes the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 to calculate the total integrity check value ICVt. The total integrity check value ICVt' is generated by using ~~as a key the~~ system signature key Ksys as a key stored in the internal memory 307 of the recording and reproducing device cryptography process section 302, to decrypt the intermediate integrity check value based on the DES, as shown in Fig. 25. Ksys is stored in the internal memory 307. Then at step S216, the generated total integrity check value ICVt' ~~generated and~~ the ICVt in the header are compared together. ~~_____~~ ~~and i~~ If they are equal, the process proceeds to step S217.

[0640] The total integrity check value ICVt and the integrity check value ICVdev unique to the recording and reproducing device are used to verify that all of the integrity check values ICVa and ICVb and the integrity check value for each content block have not been tampered with. Thus, if the total integrity check value generated by means of the above described process equals the integrity check value: ICVt or ICVdev stored in the header, it is determined that all of the integrity check values for each content block have not been tampered.

[0641] Next, at step S217, the control section 301 of the recording and reproducing device 300 reads the block data out from the recording device 400. Furthermore, at step S218, it is determined whether or not the data has ~~ve~~ been encrypted. ~~_____~~ ~~and i~~ If the data has ~~ve~~ been encrypted, the cryptography process section 302 of the recording and reproducing device

300 decrypts the block data. If the data ~~has~~^{have} not been encrypted, the process skips step S219 and advances to step S220.

[0642] Then at step S220, the control section 301 of the recording and reproducing device 300 checks whether any content block is to be verified. This is done, based on the content block information table in the block information table (BIT). If any content block is to be verified, the content integrity check value has been stored in the block information in the header. In this case, the content integrity check value ICVi for this content block is calculated at step S221. If no content block is to be verified, the process skips steps S221 and S222 to advance to step S223.

[0643] If the block has been encrypted as previously described in Fig. 36, the content integrity check value ICVi' is generated by decrypting the input content block with the content key Kcon in the DES CBC mode, exclusive-ORing all of the results every 8 bytes to generate the content intermediate value. ~~Then the process encrypts~~^{and then the process encrypts} the obtained value with the content-integrity-check-value-generating key Kicvc (stored in the internal memory 307 of the recording and reproducing device 300). Additionally, if the block has not been encrypted, the content integrity check value is generated by sequentially inputting the entire data (plain text) to the tamper-check-value-generating function shown in Fig. 36 (DES-CBC-MAC using the content-integrity-check-value-generating key Kicvc) in such a manner that 8 bytes are input each time.

[0644] At step S222, the control section 306 of the recording and reproducing device cryptography process section 302 compares the generated content integrity check value ICVi' with the ICVi stored in the content block received from the recording device 400 at step S202, and passes the result to the control section 301 of the recording and reproducing device 300. On receiving the result (and if the verification has been successful), the content plain data for execution (reproduction) on the RAM of the recording and reproducing device system is formed at step S223. The control section 301 of the recording and reproducing device 300 takes out the next

content block to be verified and causes the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 to verify this content block. Similar verification processes and RAM storage processes are repeated until all the content blocks are verified (step S224).

[0645] If the check values do not match at any of steps S204, S210, S214, S216, ~~and~~ or S222, an error occurs to end the reproduction process.

[0646] When it is determined at step S224 that all the blocks have been read out, the process proceeds to step S225 to start executing and reproducing the content (program or data).

[0647] The aspect of the process for reproducing content data of the format type 0 has been explained.

[0648] Next, the process for downloading content data of the format type 1 will be explained with reference to Fig. 43. The following description will focus on differences from the above described download process for the format type 0.

[0649] The processing from steps S201 to S217 is similar to that in the above described download process for the format type 0, so description thereof is omitted.

[0650] For the format type 1, at step S231, encrypted parts are decrypted to generate a part ICV. Further at step S232, the block ICV_i' is generated. As previously described, with the format type 1, if at least one of the parts in a block contains data to be verified with the integrity check value ICV_i, the content integrity check value ICV_i is defined for this block. For example, if the part j has been encrypted, an integrity check value P-ICV_{ij} for a part j of a block i is generated by exclusive-ORing the entire plain text (decrypted text) every 8 bytes and decrypting the obtained value with the content-integrity-check-value-generating key Kicvc. Additionally, if the part j has not been encrypted, the integrity check value P-ICV_{ij} is generated by sequentially inputting the entire data (plain text) to the tamper-check-value-generating function shown in Fig. 36 (DES-CBC-MAC using

the content-integrity-check-value-generating key Kicvc) in such a manner that 8 bytes are input each time.

[0651] Further, if the block i contains only one part having [ICV flag = subject of ICV] indicating that it is to be checked, the integrity check value P-ICVij generated using the above method is directly used as the block integrity check value ICVi. If the block i contains a plurality of parts having [ICV flag = subject of ICV] indicating that they are to be checked, the integrity check value P-ICVij is generated by connecting a plurality of parts integrity check values P-ICVij together in accordance with part numbers to obtain data. Andand the process then sequentially inputting ~~inputs~~ the entire data (plain text) to the tamper-check-value-generating function shown in Fig. 36 (DES-CBC-MAC using the content-integrity-check-value-generating key Kicvc) in such a manner that 8 bytes are input each time. This is the same as explained in Fig. 37.

[0652] For the format type 1, the content integrity check value generated by means of the above described procedure undergoes comparison at step S222. Processing at the next step S223 and the subsequent steps is similar to that for the format type 0, so description thereof is omitted.

[0653] Next, the process for reproducing content data of the format type 2 will be explained with reference to Fig. 44. The following description will focus on differences from the above described reproduction processes for the format types 0 and 2.

[0654] Steps S201 to S210 ~~is~~ are similar to that in the above_ described reproduction processes for the format types 0 and 1, so description thereof is omitted.

[0655] For the format type 2, the processing at steps S211 to S216, which is executed for the format types 0 and 1, is not executed. In addition, the format type 2 has no content integrity check value, so that verification of the content integrity check value, which is executed for the format types 0 and 1, is not executed.

[0656] In the data reproduction process for the format type 2, (performed after step S210 for verifying the integrity

check value B), the process proceeds to step S217, where the block data are read out under the control of the control section 301 of the recording and reproducing device 300. Further, at step S241, the cryptography process section 306 of the recording and reproducing device 300 decrypts the block key Kblc contained in the block data. The block key Kblc, stored in the recording device 400, has been encrypted with the content key Kcon as shown in Fig. 34. ~~and Kblc~~ is thus decrypted with the content key Kcon decrypted, which has been decrypted at the previous step S207.

[0657] Then at step S242, the block key Kblc (decrypted at step S241) is used to decrypt the block data. Furthermore, at step S243, the content (program or data) is executed and reproduced. The processing from steps S217 to S243 is repeated for all the blocks. When it is determined at step S244 that all the blocks have been read out, the reproduction process is ended.

[0658] As described above, the process for the format type 2 omits the process for verifying the integrity check value, such as the total integrity check value. It thus provides a configuration suitable for executing the decryption process at a high speed, and a format suitable for processing data such as music data which requires real-time processing.

[0659] Next, the process for reproducing content data of format type 3 will be described with reference to Fig. 45. The following description will focus on differences from the above described reproduction process for the format types 0, 1, and 2.

[0660] The process for the format type 3 essentially has many characteristics in common with that for the format type 2, ~~but~~ Format type 3 differs therefrom in that, as described in Fig. 35, the format type 3 has no content key. ~~in that~~ ~~the~~ The block key Kblc is stored in the recording device 400 after encryption with the storage key Kstr.

[0661] Between steps S201 and S210, processing at steps S251, S252, S253, and S254 is configured to omit the use of the content key, which is contrary to the corresponding processing for the formats 0, 1, and 2.

[0662] At step S251, the control section 301 of the recording and reproducing device 300 takes out, from the read-out header, the block information table key Kbit ~~encrypted with the storage key Kstr unique to the recording device~~ and then transmits this key to the recording device 400. This is done via the recording device controller 303 of the recording and reproducing device 300. Kbit is encrypted with the storage key Kstr unique to the recording device 400.

[0663] On receiving the block information table key Kbit transmitted from the recording and reproducing device 300, the recording device 400 causes the encryption/decryption section 406 of the recording device cryptography process section 401 to decrypt the received data with the storage key Kstr ~~unique to the recording device which is stored in the internal memory 405 of the recording device cryptography process section 401~~ and to then reencrypt the decrypted data using the session key Kses. Kses is unique to the recording device 400, and is stored in the internal memory 405 of the recording device cryptography process section 401. —Kses is made sharable during the—mutual authentication. This process is as previously described in detail in (9) Key Exchange Process after Mutual Authentication.

[0664] At step S252, the control section 301 of the recording and reproducing device 300 receives the block information table key Kbit (reencrypted with the session key Kses), from the recording device 400. Kbit is received via the recording device controller 303 of the recording and reproducing device 300.

[0665] Then at step S253, the control section 301 of the recording and reproducing device 300 transmits the received block information table key Kbit (reencrypted with the session key Kses), to the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300. On receiving the block information table key Kbit (reencrypted with the session key Kses the content block), the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 causes the encryption/decryption

section 308 of the recording and reproducing device cryptography process section 302 to decrypt this block information table key Kbit with the session key Kses—~~made sharable during the mutual authentication.~~

[0666] Further at step S208, the decrypted block information table key Kbit is used to decrypt the block information read out at step S202. The recording and reproducing device cryptography process section 302 of the recording and reproducing device 300 replaces the decrypted block information table key Kbit and block information table BIT with the block information table key Kbit and block information table BIT, contained in the header read out at step S202, to hold the latter. Additionally, the control section 301 of the recording and reproducing device 300 reads the decrypted block information table BIT out from the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300.

[0667] Further, at step S254, the control section 306 of the recording and reproducing device cryptography process section 302 generates the integrity check value B(ICVb') from the block information table key Kbit and the block information table (BIT). The integrity check value B, ICVb', is generated, as shown in Fig. 24, by using as a key the integrity-check-value-B-generating key Kicvb ~~stored in the internal memory 307 of the recording and reproducing device cryptography process section 302,~~ to decrypt the exclusive-ORed value comprising the block information table key Kbit and the block information table (BIT), based on the DES. Kicvb is stored in the internal memory 307 of the recording and reproducing device cryptography process section 302. Then at step S210, the integrity check value B, ICVb', and the ICVb in the header are compared together, and if they are equal, the process proceeds to step S211.

[0668] With the format type 3, the block key is further encrypted with the storage key when stored in the recording device 400, thereby requiring the recording device 400 to execute a decryption processes with the storage key and the session key Kses. It ~~and also requiring~~ requires the recording

and reproducing device 300 to execute a decryption process with the session key. This series of steps corresponds to the process steps shown as steps S255 and S256.

[0669] At step S255, the control section 301 of the recording and reproducing device 300 takes out, from the read-out header, the block key Kblc (encrypted with the storage key Kstr, which is unique to the recording device which that has been read out at step S217) and then transmits this key to the recording device 400 via the recording device controller 303 of the recording and reproducing device 300.

[0670] On receiving the block key Kblc transmitted from the recording and reproducing device 300, the recording device 400 causes the encryption/decryption section 406 of the recording device cryptography process section 401 to decrypt the received data with the storage key Kstr. ~~unique to the recording device which is stored in the internal memory 405 of the recording device cryptography process section 401 and to~~ It then reencrypts the decrypted data using the session key Kses that was made sharable during the mutual authentication. Kstr is unique to the recording device which is stored in the internal memory 405 of the recording device cryptography process section 401. This process is as previously described in detail in (9) Key Exchange Process after Mutual Authentication.

[0671] At step S256, the control section 301 of the recording and reproducing device 300 receives the block key Kblc (reencrypted with the session key Kses), from the recording device 400 via the recording device controller 303 of the recording and reproducing device 300.

[0672] Then, at step S257, the cryptography process section 306 of the recording and reproducing device 300 decrypts the block key Kblc using the session key Kses.

[0673] Then at step S242, the block key Kblc, decrypted at step S257, is used to decrypt the block data. Furthermore, at step S243, the content (program or data) is executed and reproduced. The processing from steps S217 to S243 is repeated for all the blocks. When it is determined at step S244 that

all the blocks have been read out, the reproduction process is ended.

[0674] The process for reproducing a content of the format type 3 has been described. The format type 3 is similar to the format type 2 in that the process for verifying the total integrity check value is omitted. However, format type 3, but provides a processing configuration with a higher security level due to the inclusion of the process for exchanging the block key Kblc.

(11) Process Executed by Content Provider to Generate Integrity Check Value (ICV)

[0675] In the above described embodiments, the verification processes with the various integrity check values ICV are executed during downloading or ~~reproducing~~reproduction of a content. Aspects of the process for generating the integrity check values ICV and the verification process will be described below.

[0676] First, each of the integrity check values explained in the embodiments will be described in brief. The following integrity check values, ICV, are used in the data processing apparatus according to the present invention.

[0677] Integrity check value A, ICVa÷ is the integrity check value for verifying that the content ID and usage policy in the content data have not been tampered with.

[0678] Integrity check value B, ICVb÷ is the integrity check value for verifying that the block information table key Kbit, the content key Kcon, and the block information table have not been tampered with.

[0679] Content integrity check value ICVi÷ is the integrity check value for verifying that each content block of the content has not been tampered with.

[0680] Total integrity check value ICVt÷ is the integrity check value for verifying that the integrity check value ICVa, the integrity check value ICVb, and all the integrity check values for the content blocks have not been tampered with.

[0681] Integrity check value ICVdev, unique to the recording and reproducing device 300÷ is the integrity check

value that is replaced with the total integrity check value ICVt if the localization flag is set to 1. ~~T~~that is, the content can be used only by a particular recording and reproducing device 300. ~~and that~~It is generated as an integrity check value for the previously described integrity check value A, ICVa, integrity check value B, ICVb, and integrity check value ICVi contained in each block of the content to be checked.

[0682] Depending on the format, ~~not the check value for each content block but the content itself is checked by the~~ integrity check values ICVt and ICVdev check the content itself, not the check value for each content block.

[0683] Each of the above integrity check values is used in the data processing apparatus according to the present invention. Of these integrity check values, the integrity check values A (IVCa) and B (IVCb), the total integrity check value (IVCt), and the content integrity check value are generated by a content provider (for providing content data) or a content manager (based on data to be verified), as shown, for example, in Figs. 32 to 35 and 6. ~~and They~~ are stored in the data together with the content before being provided to a user of the recording and reproducing device 300. When downloading or reproducing the content to or from the recording device, the user of the recording and reproducing device 300, ~~that is,~~ (i.e., the content user) generates verifying ICVs (based on each data to be verified), to compare them with the stored ICVs. Additionally, the integrity check value ICVdev, unique to the reproducing device 400, is replaced with the total integrity check value ICVt. ~~And It~~ is then stored in the recording device 400 if it is shown that the content can be used only by this recording and reproducing device 300.

[0684] In the ~~above~~ above-described embodiments, the processes for generating the integrity check values are principally based on the DES-CBC. The present invention, however, is not limited to the ~~above~~ above-described method, but includes various ICV-generating and -verifying process aspects. In particular, for the relationship between the

content provider or manager and the content user, the following various ICV-generating and -verifying process configurations are possible.

[0685] Figs. 46 to 48 are views ~~useful in explaining~~ illustrating a generation process executed by a generator of the integrity check value ICV and a verification process executed by a verifier.

[0686] Fig. 46 shows a configuration wherein, for example, an ICV generator (who is a content provider or manager) executes the process for generating the ICV based on the DES-CBC as described in the above embodiments. ~~and~~ It then provides the generated ICV to a recording and reproducing device user, that is, a verifier together with the content. In this case, for the verification process, the recording and reproducing device user ~~, that is, the verifier requires, for example,~~ the keys stored in the internal memory 307 (shown in Fig. 18) for generating the corresponding integrity check values. The verifier (recording and reproducing device user) who is the content user uses the integrity-check-value-generating key stored in the internal memory 307 to apply the DES-CBC to data to be verified in order to generate the integrity check values. ~~and~~ It then compares these values with stored integrity check values. In this case, each integrity-check-value-generating key is configured so as to be secretly shared by the ICV creator and the verifier.

[0687] Fig. 47 shows a configuration wherein the ICV creator (who is the content provider or manager) generates ICVs using a digital signature of a public key cryptosystem and then provides the generated ICVs to the content user. ~~that is, the verifier together with the content and wherein the content user, that is, t~~ The verifier content user stores the public key of the ICV creator and uses this key to verify the ICVs. In this case, the public key of the ICV creator, which is held by the content user (recording and reproducing device user), ~~that is, the verifier need not be secret, this resulting results~~ in easier management. This aspect is thus suitable for ICV generation and management executed at a high

security management level, for example, that executed in one entity.

[0688] In Fig. 48, the ICV creator (who is the content provider or manager) generates ICVs using a digital signature of a public key cryptosystem. It then provides the generated ICVs to the content user, ~~that is, the verifier~~ together with the content; ~~it~~ further stores a public key ~~used by the verifier for verification,~~ in a public key certificate (see, for example, Fig. 14); ~~it~~ and then provides this key to the recording and reproducing device user, ~~that is, the verifier~~. With a plurality of ICV creators, each creator has a key managing center create data (a public key certificate) for certifying the validity of the public key.

[0689] The content user ~~who is~~ (the ICV verifier) has a public key of the key managing center. The ICV verifier verifies the public key certificate using the public key of the key managing center, and, if its validity has been ascertained, takes out the public key of the ICV creator stored in the public key certificate ~~if its validity has been ascertained~~. The verifier further verifies the ICVs using the taken-out public key of the ICV creator.

[0690] This method is ~~an aspect~~ useful if a plurality of ICV creators are present and if a center for managing these creators has an established management system.

(12) Configuration for Generating Cryptography Process Keys Based on Master Keys

[0691] A configuration for generating various cryptography process keys based on the master keys, ~~which configuration is characteristic of the present data processing system,~~ will be described below.

[0692] As previously described with reference to Fig. 18, the internal memory 307 of the recording and reproducing device 300 in the present data processing apparatus stores the various master keys. E, each of the various master keys which ~~is~~ can be used, for example, to generate the authentication key K_{ate} (see Equation 3) or the distribution key K_{dis} (see Equation 4).

[0693] When cryptography communication, mutual authentication, MAC generation, verification, or the like is carried out between two entities, ~~that is, the content provider and the content provider, or the recording and reproducing device 300 and the recording device 400 in the present data processing apparatus,~~ these entities conventionally hold secret information common to them, ~~for example~~ such as, key information. The entities may be, for example, the content provider, the recording and reproducing device 300 and the recording device 400 in the present data processing apparatus. Additionally, when the above process is carried out between one and many entities, (for example, one content provider and many content users, or one recording and reproducing device and many recording media,) these entities conventionally store and hold secret information common to all the entities. ~~That is,~~ That is, secret information common to many content users or many recording media, or one content provider individually manages and uses secret information (ex. key) for each of many content users.

[0694] With the one-to-many relationship as described above, however, the configuration owning secret information (key) shared by all the entities is disadvantageous in that leakage of the secret from one entity affects all the other entities using the same secret information (ex. key). In addition, when one manager, ~~for example,~~ such as a content provider individually manages and uses secret information for each content user, a list is required ~~which that~~ which that serves to identify all the users and ~~which that~~ which that associates this identification data with unique secret information (ex. keys), ~~—~~. This thereby advantageously increasing increases list maintaining and managing burdens in proportion to the number of users.

[0695] The data processing apparatus according to the present invention has solved ~~such a conventional~~ problem with ~~the sharing of~~ secret information between entities using a configuration for holding the master keys and generating various individual keys therefrom. This configuration will be described below.

[0696] In the data processing apparatus according to the present invention, if different individual keys are required for various cryptography processes, authentication processes, and the like between recording devices, media storing contents, or recording and reproducing devices, these individual keys are generated using individual information such as identifier data (ID) unique to the devices or media and an individual-key generating method (previously determined in the recording and reproducing device 300). With this configuration, if any individual key generated should be identified, damage to the entire system can be precluded by preventing the corresponding master key from leaking. In addition, the configuration for generating the keys from the master keys eliminates the needs for the association list.

[0697] A specific example of configuration will be described with reference to the drawings. Fig. 49 ~~is a view useful in explaining the~~ illustrates a configuration for generating various keys using the various master keys held by the recording and reproducing device 300. The medium 500 and the communication means 600 ~~in Fig. 49~~ input contents as in the already described embodiments. The content is encrypted by the content key Kcon, which is in turn encrypted by the distribution key Kdis.

[0698] For example, if the recording and reproducing device 300 attempts to take a content out from the medium 500 or the communication means 600 and download it to the recording device 400, the recording and reproducing device 300 must obtain the distribution key Kdis that has encrypted the content key as previously described in Figs. 2 and 39 to 41. Although the key Kdis can be directly obtained from the medium 500 or the communication means 600 or the recording and reproducing device 300 can obtain and store it in its memory beforehand, the configuration for distributing such a key to many users may be subjected to leakage, which may affect the entire system, as described above.

[0699] The data processing system according to the present invention is configured to generate the distribution key Kdis by applying a master key MKdis for the distribution key stored

in the memory of the recording and reproducing device 300 as well as a process based on the content ID, ~~that~~ That is, $Kdis = DES (MKdis, \text{content ID})$, as shown in the lower part of Fig. 49. In a content distributing configuration between a content provider providing contents from the medium 500 or the communication means 600 and the recording and reproducing device 300, (where recording and reproducing device 300 which is a content user), despite a large number of content providers, this configuration enables advanced security to be maintained without the need to distribute the individual distribution keys Kdis via the medium 500, the communication means 600, or the like, or to store them in each recording and reproducing device 300.

[0700] Next, the generation of the authentication key Kakae will be explained. In downloading a content from the recording and reproducing device 300 to the recording medium 400 (as previously described in Figs. 22 and 39 to 41), or causing the recording and reproducing device 300 to execute and reproduce a content stored in the recording medium 400 (as described in Figs. 42 to 45), the recording and reproducing device 300 and the recording medium 400 must execute the mutual authentication process (see Fig. 20).

[0701] As described in Fig. 20, this authentication process requires the recording and reproducing device 300 to have the authentication key Kake. Although the recording and reproducing device 300 can obtain the authentication key directly from, for example, the recording medium 400 or can obtain and store it in its memory beforehand, the configuration for distributing such a key to many users may be subjected to leakage. Leakage, ~~which~~ may affect the entire system, as in the above—described configuration for the distribution key.

[0702] The data processing system according to the present invention is configured to obtain the authentication key Kake by applying a master key MKake for the distribution key stored in the memory of the recording and reproducing device 300, as well as a process based on the recording device ID: IDmem, ~~that~~.

~~That that~~ is, $Kake = DES (MKake, IDmem)$, as shown in the lower part of Fig. 49.

[0703] Further, in downloading a—content from the recording and reproducing device 300 to the recording medium 400 (as previously described in Figs. 22 and 39 to 41) or causing the recording and reproducing device 300 to execute and reproduce a—content stored in the recording medium 400 (as described in Fig. 28, Figs. 42 to 45), a configuration similar to that for the distribution or authentication key described above can be used for the recording and reproducing device signature key $Kdev$ that is required to generate the integrity check value $ICVdev$ unique to the recording and reproducing device 300 if the content can be used only by a particular recording and reproducing device 300. In the above described embodiments, the recording and reproducing device signature key $Kdev$ is stored in the internal memory, ~~—~~. ~~However, but~~ if the master key $Mkdev$ for the recording and reproducing device signature key is stored in the memory whereas the recording and reproducing device signature key $Kdev$ is not stored therein, and if the recording and reproducing device signature key $Kdev$ is obtained by means of $Kdes = DES (MKdev, IDdev)$ based on the recording and reproducing device identifier $IDdev$, and the master key $MKdev$ for the recording and reproducing device signature key, as required, (as shown in the lower part of Fig. 49), then it advantageously becomes unnecessary for each apparatus to have the recording and reproducing device signature key $Kdev$.

[0704] In this manner, the data processing apparatus according to the present invention is configured to sequentially generate information from the master keys and each ID , ~~—~~. The information is, for example, ~~—such as—~~ a key which is required for the cryptography information process between two entities. ~~such as~~ The entities may be, by way of example, the provider and the recording and reproducing device 300, or the recording and reproducing device 300 and the recording device 400. Consequently, even if the key information leaks from each entity, the range of damage incurred by the individual keys is further limited. It ~~—and~~

~~it~~ also becomes unnecessary to manage key lists for the individual entities as described above.

[0705] A plurality of examples of processes relating to this configuration will be explained ~~by showing a flow~~ with flowcharts. Fig. 50 shows examples of a process executed by the content producer or manager to decrypt ~~a content~~ or the like using a master key. Fig. 50 also illustrates ~~and a~~ process executed by a user device, (for example, the recording and reproducing device 300 in the above described embodiment) to decrypt the encrypted data using the master key.

[0706] At step S501, a content producer or manager imparts an identifier (content identifier) to ~~a content~~. At step S502, the content producer or manager generates a key for encrypting ~~a content~~ or the like, based on its owned master key and a content ID. At this step, if the distribution key Kdis is to be generated, it is generated based on the ~~above~~ above-described Kdis = DES (MKdis, medium ID). Then at step S503, the content producer or manager uses a key (for example, the distribution key Kdis) to encrypt part or all of the content stored in the medium. The content producer supplies the content encrypted through these steps, via the medium 500 such as a DVD, the communication means 600, or the like.

[0707] ~~On the other hand, a~~ At step S504, a user device (such as the recording and reproducing device 300) reads the content ID from the content data received via the medium 500 such as a DVD, the communication means 600, or the like. Then at step S505, the user device generates a key applied to decryption of the encrypted content based on the read-out medium ID and its owned master key. If the distribution key Kdis is to be obtained, this generation process corresponds to, for example, the distribution key Kdis = DES (MKdis, medium ID). At step S506, the user device uses this key to decrypt the content, ~~and a~~ At step S507, ~~uses, that is, the user devices~~ reproduces the decrypted content or execute the program.

[0708] In this example, as shown in the lower part of Fig. 50, both the content producer or manager and the user device have the master key (for example, the distribution-key-

generating master key MKdis) to sequentially generate the distribution key required to encrypt or decrypt the content based on their owned master key and each ID (medium ID).

[0709] With this system, if the distribution key leaks to a third person, the third person can decrypt that content. However, ~~but~~ contents stored in other media 500 with different content IDs can be prevented from decryption. This thereby ~~minimizing~~ minimizes the adverse effects of the leakage of one content key on the entire system. Additionally, this system does not require the user device, (that is, the recording and reproducing device 300) to hold a key associating list for each medium 500.

[0710] An example where the content producer or manager holds a plurality of master keys to execute a process depending on a content distribution destination is provided with reference to Figs. 51-52.

[0711] In Fig. 51, Step-step S511, executed by the content producer or manager, comprises imparting an identifier (content ID) to the content. Step S512 comprises selecting one of a plurality of master keys (for example, a plurality of distribution-key-generating master keys MKdis) held by the content producer or manager. Although described in further detail with reference to Fig. 52, this selection process comprises setting an applied master key beforehand for each of the countries to which content users belong, each apparatus type, or each apparatus version, and executing the master keys in accordance with the settings.

[0712] Then at step S513, the content producer or manager generates an encryption key based on the master key selected at step S512 and the content ID determined at step S511. If, for example, the distribution key Kdis is to be generated, it is generated based on the above described Kdis = DES (MKdis, medium ID). Then at step S514, the content producer or manager uses a key (for example, the distribution key Kdisi) to encrypt part or all of the content stored in the medium. At step S515, the content producer distributes the encrypted content via the medium 500 such as a DVD, the communication means 600, or the like, using a distribution unit. The

distribution unit comprising comprises the content ID, the master-key-generating information used, and the encrypted content.

[0713] On the other hand, at step S516, for example, the user device (such as a recording and reproducing device 300) determines whether or not it holds the master key corresponding to the master key ID in the content data distributed by the medium 500 (such as a DVD) or by the communication means 600. If it does not have the master key corresponding to the master key ID in the content data, the distributed content cannot be used by this user device and the process is ended.

[0714] If the user device has the master key corresponding to the master key ID in the content data, then at step S517, it reads the content ID out from the content data received via the medium 500, the communication means 600, or the like. Then at step S518, the user device generates a key applied to decryption of the encrypted content based on the read-out content ID and its held master key. This process is a distribution-key $K_{disi} = DES (Mk_{disi}, \text{contents ID})$ if it intends to get a distribution key K_{disi} . At step S519, ~~contents are~~ is decrypted by means of the K_{disi} key. At step S520 ~~decrypted contents are used, that is, reproduction or program is performed.~~

[0715] In this example, as shown in the lower part of Fig. 51, the content producer or manager has a master key set comprising a plurality of master keys, —. The master key set includes, for example, distribution-key-generating master keys MK_{disi} 1 to MK_N . On the other hand, the user device has one master key. —, For example, the user device has one distribution-key-generating master key MK_{disi} so that it can decrypt the content only when the content producer or manager has used the key MK_{disi} for the encryption.

[0716] Fig. 52 shows an example where master keys ~~varying~~ depending on the country ~~is applied~~, as a specific example of the aspect shown in the flow in Fig. 51. The content provider has master keys $MK1$ to MKN , of which the key $MK1$ is used to generate keys for encrypting contents distributed to user

devices for Japan. For example, an encryption key K1 is generated from a content ID and the key MK1 and then ~~user-used~~ to encrypt ~~a-content~~. The master keys MK1 to ~~n-MKN~~ are further set such that the key MK2 is used to generate keys for encrypting contents distributed to user devices for the U.S., and the key MK3 is used to generate keys for encrypting contents distributed to user devices for the EU (Europe).

[0717] ~~On the other hand, f~~For user devices for ~~Japan, Japan,~~ for instance, specifically, ~~recording and reproducing devices~~ 300 such as PCs or game apparatuses which are sold in Japan, the master key MK1 is stored in their internal memories, for user devices for the U.S., the master key MK2 is stored in their internal memories 307, and for user devices for the EU, the master key MK3 is stored in their internal memories 307.

[0718] With this configuration, the content provider selectively uses one of the master keys MK1 to ~~n-MKN~~ depending on user devices that can use one a-content, in order to encrypt the content to be distributed to the user devices. For example, to allow the content to be used only by the user devices for Japan, the master key K1 (generated using the master key MK1) is used to encrypt the content. This encrypted content can be decrypted using the master key MK1 stored in the user devices for Japan, ~~—~~. That is, MK1 allows a decryption key to be generated, ~~—~~. In contrast, ~~whereas~~ the key K1 cannot be obtained from the master keys MK2 and MK3 (stored in the user devices for the U.S. and EU, respectively), thereby preventing the encrypted content from being decrypted.

[0719] In this manner, the content provider can selectively use a plurality of master keys to set localization for various contents. Fig. 52 shows an example where the different master keys are used for the different countries to which the user devices belong, but various use forms are possible, ~~—~~. For example, the master key can be switched depending on the type of the user device or its version, as described above.

[0720] Next, Fig. 53 shows an example of a process where an identifier unique to a medium 500, ~~that is, (i.e., a medium ID)~~ and a master key are combined together. Here, the medium 500 refers to, for example, DVDs or CDs in which contents ~~are is~~

stored. The medium ID may be unique to individual media 500, the titles of contents such as movies, or individual medium manufacturing lots. In this manner, medium IDs may be assigned in various manners.

[0721] At step S521, a medium producer or manager determines an identifier (medium identifier) for a medium 500. At step S522, the medium producer or manager generates a key for encrypting a content stored in the medium 500 based on its owned master key and a medium ID. At this step, if, for example, the distribution key Kdis is to be generated, it is generated based on the above described $Kdis = DES (MKdis, \text{medium ID})$. Then at step S523, the medium producer or manager uses a key (for example, the distribution key Kdis) to encrypt part or all of the content stored in the medium 500. The medium producer supplies, through these steps the medium 500 storing the content encrypted ~~through these steps~~.

[0722] On the other hand, at step S524, a user device such as the recording and reproducing device 300 reads the medium ID from the supplied medium 500. Then at step S525, the user device generates a key applied to decryption of the encrypted content based on the read-out medium ID and its owned master key. If the distribution key Kdis is to be obtained, this generation process corresponds to, for example, the distribution key $Kdis = DES (MKdis, \text{medium ID})$. At step S526, the user device uses this key to decrypt the content, ~~and a~~ At step S527, uses, the user device uses the content. that That is, the user device reproduces the decrypted content or executes the program.

[0723] In this example, as shown in the lower part of Fig. 53, both the medium producer or manager and the user device have the master key (for example, the distribution-key-generating master key MKdis) to sequentially generate the distribution key required to encrypt or decrypt the content based on their owned master key and each ID (medium ID).

[0724] With this system, if any medium key leaks to a third person, the third person can decrypt the content in the medium 500, but contents stored in other media 500 with different medium IDs can be prevented from decryption, ~~thereby~~ This

minimizes~~ing~~ the adverse effects of the leakage of one medium key on the entire system. Additionally, this system does not require the user device, that is, the recording and reproducing device 300, to hold a key associating list for each medium 500. Further, the size of a-content encrypted with one medium key is limited to a capacity that can be stored within that medium 500, so that there is a slim possibility that the content reaches the amount of information required to attack the encrypted text. ~~thereby~~This further reduces~~ing~~ the possibility of decrypting the encrypted text.

[0725] Next, Fig. 54 shows an example of a process where an identifier unique to the recording and reproducing device 300, ~~that is, a recording and reproducing device ID~~ and a master key are combined together.

[0726] At step S531, a recording and reproducing device user generates a key for encrypting a-content or the like based on a master key and a recording and reproducing device ID. This information can be stored, for example, in the internal memory 307 of the recording and reproducing device 300. If, for example, the content key Kcon is to be obtained, this generation process corresponds to $Kcon = DES (MKcon, \text{recording and reproducing device ID})$. Then at step S532, the user uses a key (for example, the distribution key Kcon) to decrypt the content. At step S533, the user stores the encrypted content in the recording and reproducing device 300, such as a hard disk.

[0727] On the other hand, when the recording and reproducing device user that has stored the content requests the stored data to be recovered, a system manager for managing the recording and reproducing device 300 reads a recording and reproducing device ID from the recording and reproducing device in step S534. Then at step S535, the system manager generates a key applied to recovery of the encrypted content, based on the read-out recording and reproducing device ID and its owned master key. If the content key Kcon is to be obtained, this generation process corresponds to, for example, the content key $Kcon = DES (MKcon, \text{recording and reproducing device ID})$.

device ID). At step S536, the user device uses this key to decrypt the content.

[0728] In this example, as shown in the lower part of Fig. 54, both the recording and reproducing device user and the system manager have the master key (for example, the content-key-generating master key MKcon) to sequentially generate the distribution key required to encrypt or decrypt the content based on their owned master key and each ID (recording and reproducing device ID).

[0729] With this system, if the content key leaks to a third person, the third person can decrypt that content, but contents stored in other media 500 with different recording and reproducing device IDs can be prevented from decryption. This, thereby minimizing the adverse effects of the leakage of one content key on the entire system. Additionally, this system does not require the system manager or the user device to hold a key associating list for each medium 500.

[0730] Fig. 55 shows a configuration wherein an authentication key used for a mutual authentication process between a slave device, (for example, the recording and reproducing device 400, such as a memory card) and a host device, (for example, the recording and reproducing device 300) is generated based on a master key. Although in the previously described authentication process (see Fig. 20), the authentication key is stored in the internal memory 405 of the slave device in advance, it can be generated during the authentication process based on the master key as shown in Fig. 55.

[0731] For example, at step S541, the slave device that is the recording device 400 generates, as an initialization process before starting the authentication process, the authentication key Kake. Kake is for use in the mutual authentication process based on the master key and slave device ID stored in the internal memory 105 of the slave device that is the recording device 400. The authentication key is generated based on Kake = DES (MKake, slave device ID). Then at step S542, the generated authentication key is stored in the memory.

[0732] On the other hand, at step S543, the host device such as the recording and reproducing device 300, reads a slave device ID out from the installed recording device 400, (that is, the slave device), via the communication means. Then at step S544, the host device generates a authentication key applied to a mutual authentication process based on the read-out slave device ID and its owned authentication-key-generating master key. This generation process corresponds to, for example, the authentication key $Kake = DES (MKake, \text{slave device ID})$. At step S545, this authentication key is used to execute the authentication process.

[0733] In this example, as shown in the lower part of Fig. 55, both the slave device and the master device have the master key, (that is, the authentication-key-generating master key $Mkake$) to sequentially generate the distribution key required for the authentication process based on their owned master key and the slave device ID.

[0734] With this system, if the authentication key leaks to a third person, this authentication key is effective only on the corresponding slave device and authentication is not established with other slave devices, thereby minimizing the adverse effects of the leakage of the key.

[0735] As described above, the data processing apparatus according to the present invention is configured so that the information such as the key which is required for the procedure for the cryptography information process between the two entities such as the content provider and the recording and reproducing device, or the recording and reproducing device and the recording device. Thus, even if the key information leaks from each entity, the range of damage incurred by the individual keys is further limited, ~~and it~~ It also becomes unnecessary to manage key lists for the individual entities as described above.

(13) Control of Cryptography Intensity in Cryptography Process

[0736] In the above described embodiments, the cryptography process between the recording and reproducing device 300 and the recording device 400 is principally described in

conjunction with the example using the cryptography process based on the single DES configuration described with reference to Fig. 7. The encryption process method applied to the present data processing apparatus is not limited to the above described Single DES. ~~____, but a~~Any encryption method may be employed depending on a required security state.

[0737] For example, the Triple DES method, configured as shown in the previously described Figs. 8 to 10, is applicable. For example, both the cryptography process section 302 of the recording and reproducing device 300 and the cryptography process section 401 of the recording device 400 shown in Fig. 3 can be configured so as to execute the Triple DES method so that a process can be executed which corresponds to the cryptography process based on the Triple DES method described in Figs. 8 to 10.

[0738] The content provider, however, may give top priority to processing speed (dependent on the content) to use a 64-bit content key Kcon based on the Single DES method, or gives top priority to security to use a 128- or 192-bit content key Kcon based on the Triple DES method. Accordingly, it is not preferable to configure the cryptography process section 302 of the recording and reproducing device 300 and the cryptography process section 401 of the recording device 400 so as to accommodate only one of the Triple and Single DES methods. Therefore, the cryptography process section 302 of the recording and reproducing device 300 and the cryptography process section 401 of the recording device 400 are desirably configured so as to accommodate both the Triple and Single DES methods.

[0739] However, to configure the cryptography process section 302 of the recording and reproducing device 300 and the cryptography process section 401 of the recording device 400 so as to execute both the Triple and Single DES methods, different circuits and logics must be configured for these cryptography process sections. For example, to allow the recording device 400 to execute a process corresponding to the Triple DES, a command set for the Triple DES must be stored in the command register as shown in ~~the above~~ Fig. 29. This may

complicate the process section configured in the recording device 400.

[0740] Thus, for the present data processing apparatus, a configuration is proposed wherein the logic of the cryptography process section 401 of the recording device 400 is configured to accommodate the Single DES, while executing a process corresponding to the Triple DES process to store data (keys, contents, or the like) encrypted based on the Triple DES method—, in the external memory 402 of the recording device 400.

[0741] For example, ~~in the example~~ for the data format type 0 shown in Fig. 32, when content data ~~are~~ is downloaded from the recording and reproducing device 300 to the recording device 400, the authentication process is executed at step S101 in ~~the previously described~~ Fig. 39 (showing the flow of downloading data of the format type 0), and the session key Kses is generated. Further, at step S117, the cryptography process section 302 of the recording and reproducing device 300 encrypts the content key Kcon with the session key Kses. It then—and—transmits the encrypted key to the recording device 400 via the communication means 600. At step S118, the cryptography process section 403 of the recording device 400, (which has received the encrypted key), decrypts the content key Kcon with the session key Kses. Cryptography process section ,403 then further encrypts it with the storage key Kstr, and transmits the resulting key to the cryptography process section 302 ~~of the recording and reproducing device 300~~. The recording and reproducing device 300 subsequently forms a data format (step S121). It—and transmits formatted data to the recording device 400, and T—the recording device 400 stores the received data in the external memory 402.

[0742] If the cryptography process executed between steps S117 and S118 of the above process (by the cryptography process section 401 of the recording device 400) ~~between steps S117 and S118 of the above process~~ is configured to selectively execute either the Single or Triple DES method, the cryptography process section 401 works whether the content

provider provides content data using the content key Kcon in accordance with the Triple DES or the Single DES.

[0743] Fig. 56 ~~shows a flow useful in explaining~~illustrates a configuration for executing the cryptography process method in accordance with the Triple DES method~~,—~~. This is done using both the cryptography process section 302 of the recording and reproducing device 300 and the cryptography process section 401 of the recording device 400. Fig. 56 shows an example of a process for encrypting the content key Kcon with the storage key Kstr. The~~which~~ process is executed in downloading content data from the recording and reproducing device 300 to the recording device 400~~.—~~wherein~~—~~The content key Kcon is based on the Triple DES method. Here, the example of the process for the content key Kcon is shown, but other keys or other data~~, such as contents—content,~~ can be similarly processed.

[0744] The Triple DES method uses two or three keys in such a manner that a 64-bit key is used for the Single DES, while a 128- or 192-bit key is used for the Triple DES, as previously described in Figs. 8 to 10. These three content keys Kcon are referred to as Kcon1, Kcon2, and (Kcon3) or, alternatively, Kc1, Kc2 and (Kc3) as shown in Fig. 56. The Kcon3 is shown in the parentheses because it may not be used.

[0745] The process in Fig. 56 will be explained as follows. At step S301, the mutual authentication process is carried out between the recording and reproducing device 300 and the recording device 400. This mutual authentication process step is executed during the process as in the previously described Fig. 20. During this authentication process, the session key Kses is generated.

[0746] Once the authentication process at step S301 has been completed, the integrity check values ICV (including the integrity check values A and B, the content integrity check value, and the total integrity check value) are collated.

[0747] When all the check values, {ICV}, have been collated, and it has been determined that no data have been tampered with, the process proceeds to step S303. In step S303, ~~where~~ the control section 306 of the recording and reproducing device cryptography process section 302 ~~of the recording and~~

~~reproducing device 300~~ uses the encryption/decryption section 308, ~~of the recording and reproducing device cryptography process section 302~~ as well as the previously obtained or generated distribution key Kdis, to decrypt the content Kcon. Kcon may be stored in the header section of the data obtained from the medium 500, or received from the communication means 600 via the communication section 305. The content key in this case is a triple DES type key, such as content keys Kcon1, Kcon2, and (Kcon3).

[0748] Then at step S304, the control section 306 of the recording and reproducing device cryptography process section 302 causes the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 to encrypt only the content key Kcon1 of the content keys Kcon1, Kcon2, and (Kcon3) ~~decrypted at step S303,~~. This is done using the session key Kses made sharable during the mutual authentication.

[0749] The control section 301 of the recording and reproducing device 300 reads data containing the content key Kcon1 (encrypted with the session key Kses,). The data is read out from the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300. The control section 301 then transmits the data to the recording device 400 via the recording device controller 303 of the recording and reproducing device 300.

[0750] Then at step S305, (on receiving the content key Kcon1 transmitted from the recording and reproducing device 300), the recording device 400 causes the encryption/decryption section 406 of the recording device cryptography process section 401 to decrypt the received content key Kcon1 using the session key Kses. Kses was made sharable during the mutual authentication. Further at step S306, the recording device 400 causes the encryption/decryption section 406 to reencrypt the decrypted content key with the storage key Kstr. Kstr is unique to the recording device 400. It~~which~~ is stored in the internal memory 405 of the recording device cryptography process,. The

recording device 400—and then transmits the reencrypted key to the recording and reproducing device 300 via the communication section 404.

[0751] Then at step S307, the control section 306 of the recording and reproducing device cryptography process section 302 causes the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 to encrypt only the content key Kcon2 of the content keys Kcon1, Kcon2, and (Kcon3). This is ~~decrypted at step S303,~~ using done using the session key Kses, which was made sharable during the mutual authentication.

[0752] The control section 301 of the recording and reproducing device 300 reads data containing the content key Kcon2 encrypted with the session key Kses, out from the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300. The control section 301 then transmits thiese data to the recording device 400 via the recording device controller 303 of the recording and reproducing device 300.

[0753] Then at step S308, on receiving the content key Kcon2 transmitted from the recording and reproducing device 300, the recording device 400 causes the encryption/decryption section 406 of the recording device cryptography process section 401 to decrypt the received content key Kcon2. It is decrypted using the session key Kses, which was made sharable during the mutual authentication. Further at step S309, the recording device 400 causes the encryption/decryption section 406 to reencrypt the decrypted content key with the storage key Kstr. Kstr is unique to the recording device, —which and is stored in the internal memory 405 of the recording device cryptography process section 401, —. Recording device 400 and then transmits the reencrypted key to the recording and reproducing device 300 via the communication section 404.

[0754] Then at step S310, the control section 306 of the recording and reproducing device cryptography process section 302 causes the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 to encrypt only the content key Kcon3 of the content keys

Kcon1, Kcon2, and (Kcon3). ~~decrypted at step S303,~~ This is performed using the session key Kses, which was made sharable during the mutual authentication.

[0755] The control section 301 of the recording and reproducing device 300 reads data containing the content key Kcon3 (encrypted with the session key Kses), out from the recording and reproducing device cryptography process section 302 of the recording and reproducing device 300. The control section 301 then transmits ~~these~~ this data to the recording device 400 via the recording device controller 303 of the recording and reproducing device 300.

[0756] Then at step S311, ~~on receiving the content key Kcon3 transmitted from the recording and reproducing device 300,~~ the recording device 400 causes the encryption/decryption section 406 of the recording device cryptography process section 401 to decrypt the received content key Kcon3 using the session key Kses ~~made sharable during the mutual authentication.~~ This is done on receiving the content key Kcon3 that is transmitted from the recording and reproducing device 300. Further, at step S312, the recording device 400 causes the encryption/decryption section 406 to reencrypt the decrypted content key with the storage key Kstr. Kstr is unique to the recording device, and ~~which~~ is stored in the internal memory 405 of the recording device cryptography process. Recording device 400, ~~and~~ then transmits the reencrypted key to the recording and reproducing device 300 via the communication section 404.

[0757] Then at step S313, the cryptography process section of the recording and reproducing device 300 forms the various data formats described in Figs. 32 to 35 and transmits them to the recording device 400.

[0758] Finally, at step S314, the recording device 400 stores the received formatted data in the external memory 402. ~~These~~ This format data contains the content keys Kcon1, Kcon2, and (Kcon3) that were encrypted with the storage key Kstr.

[0759] This process enables the content keys stored in the recording device 400 to be stored as keys based on the Triple

DES cryptosystem. If only two content keys Kcon1 and Kcon2 are used, the processing from steps S310 to S312 is omitted.

[0760] As described above, the recording device 400 can store the keys with the Triple DES applied thereto in the memory by repeating processing of the same aspect, ~~that is,~~ that is, the process steps ~~at steps~~ S305 and S306 can be performed plural times with only the target changed. If the Single DES is applied to the content keys Kcon, steps S305 and S306 may be executed to carry out the formatting process at step S313 before storing the keys in the memory. Such a configuration may store commands for executing the processing at steps S305 and S306 in the command register, as in the previously described Fig. 29, and execute this processing one to three times depending on the aspect of the key, ~~that is,~~ that is, repeating the processing depends upon whether the key is based on the Triple or Single DES method. Accordingly, the processes based on both the Triple and Single DES methods can be executed without containing the Triple DES process method in the process logic of the recording device 400. In this regard, the cryptosystem may be recorded in the usage policy in the header section of the content data so as to be determined by referencing the usage policy.

(14) Program Activation Process Based on Activation Priority in Usage Policy in Content Data

[0761] As understood from the content data configurations in the previously described Figs. 4 to 6, the usage policy stored in the header section of the content data used in the present data processing apparatus contains the content type and the activation priority. With a plurality of accessible content data recorded in various recording media 500 such as the recording device 400, a DVD, a CD, a hard disk, or a game cartridge, the recording and reproducing device 300 in the present data processing apparatus determines the order in which these contents are activated, in accordance with the activation priority.

[0762] The recording and reproducing device 300 executes the mutual authentication with various recording devices 400,

such as ~~each recording device~~ a DVD device, a CD drive device, and a hard disk drive device. Recording and reproducing device 300 ~~and then~~ executes the program in the content data with the top priority in accordance with the priority in the content data. The "Program Activation Process Based on Activation Priority in Usage Policy in Content Data" will be explained below.

[0763] The above description of the present data processing apparatus focuses on the process executed if the recording and reproducing device 300 reproduces and executes content data from ~~the one~~ recording device 400. However, the recording and reproducing device 300 is generally configured so as to access, in addition to the recording device 400, a DVD, a CD, and a hard disk via the read section 304 as well as recording media 500 (such as a memory card and a game cartridge) ~~which that~~ are connected via the PIO₁₁₁ or SIO₁₁₂. In Fig. 2, only one read section 304 is described in order to avoid complicating the drawing, ~~—~~. ~~The~~ recording and reproducing device 300 can have different recording media 500, for example, a DVD, a CD, a floppy disk, and a hard disk, installed therein in parallel.

[0764] The recording and reproducing device 300 can access a plurality of recording media 500, each of which store content data. Content data supplied by an external content provider, such as a CD, are stored in the medium 500 in the data configuration shown in the previously described Fig. 4 or in each recording medium 500 (such as a memory card) in the content data configuration shown in Figs. 26 or 27, if the data are taken out from the medium 500 or downloaded via the communication means 600. Furthermore, ~~specifically,~~ ~~the content data are~~ is stored on the medium 500 and the recording device 400 in different formats depending on the format type thereof, as shown in Figs. 32 to 35. In either case, the usage policy in the header of the content data contains the content type and the activation priority.

[0765] A process executed by the recording and reproducing device 300, to activate ~~a~~ content if a plurality of content data ~~are~~ is accessible, will be explained in accordance with the ~~flow~~ Fig. 57.

[0766] Fig. 57 shows a process flow showing an example (1) of a process where there is a plurality of contents that can be activated. At step S611, recording devices 400 that are accessible to the recording and reproducing device 300 are authenticated. The accessible recording devices 400 include a memory card, a DVD device, a CD drive, a hard disc device, and a game cartridge or the like. ~~which is~~ They are connected, for example, via the parallel I/O, PIO_111, or the serial I/O, SIO_112, as shown in Fig. 2. Each recording device is authenticated under the control of the control section 301 shown in Fig. 2, for example, in accordance with the procedure previously explained in Fig. 20.

[0767] Next, at step S612, programs that can be activated are detected from the content data stored in the memory of the successfully authenticated recording device 400. Specifically, this is executed as a process of extracting contents for which the content type contained in the usage policy of the content data indicates a program.

[0768] Then at step S613, the priority of the program that can be activated and which has been extracted at step S612 is determined. Step S613 selects the top priority. Specifically, this corresponds to a process of comparing the priorities contained in the usage policies in the headers of the plurality of content data that can be activated in step S612, ~~to select the top priority.~~

[0769] Then at step S614, the selected program is activated. If the plurality of programs that can be activated have the same priority, default priorities are set for the recording devices 400 so that the content program stored in the device with the top priority is executed.

[0770] Fig. 58 shows an example (2) of a process where identifiers are set for a plurality of recording devices 400 so that the authentication and the retrieval of a content program are sequentially executed for the recording devices 400 with the identifiers, ~~—~~. Tthat is, Fig 58 illustrates a process for a plurality of contents that can be activated.

[0771] At step S621, recording devices 400 (i) installed in the recording and reproducing device 300 are authenticated. A

plurality of (n) recording devices 400 are sequentially imparted with identifiers 1 to n.

[0772] At step S622, it is determined whether or not the authentication at step S621 has been successful. ~~If, and if~~ so, the process proceeds to step S623, where programs that can be activated are retrieved from the recording media of the recording devices 400 (i). If the authentication has failed, the process proceeds to step S627 where it is determined whether or not there is a new recording device 400 from which ~~a~~ content can be retrieved. Without such a recording device 400, the process is ended, ~~and~~ otherwise, the process advances to step S628 to update the recording device identifier i and repeat step S621 and the subsequent authentication process steps.

[0773] At step S623, programs that can be activated are detected from the content data stored in the recording devices 400 (i). Specifically, this is executed as a process of extracting contents for which the content type contained in the usage policy of the content data indicates a program.

[0774] At step S624, it is determined whether or not the contents (of which the content type is a program) ~~have~~ has been extracted. If such contents ~~has~~ have been extracted, one of the extracted programs which has the top priority is selected at step S625, and the selected program is executed at step S626.

[0775] If it is determined at step S624 that no content (of which the content type is a program) has been extracted, the process proceeds to step S627 to determine whether or not there is a new recording device 400 from which ~~a~~ content can be retrieved. Without such a recording device 400, the process is ended, ~~and~~ otherwise, the process proceeds to step S628 to update the recording device identifier i and repeat step S621 and the subsequent authentication process steps.

[0776] Fig. 59 ~~shows a process flow showing~~ illustrates an example of a process for a plurality of contents that can be activated. At step S651, recording devices 400 that are accessible to the recording and reproducing device 300 are authenticated. For instance, an Accessible DVD device, CD

drive, hard disc device, and game cartridge or the like are authenticated. Each recording device 400 is authenticated under the control of the control section 301 (shown in Fig. 2, —). This is done, for example, in accordance with the procedure previously explained in Fig. 20.

[0777] Next, at step S652, programs that can be activated are detected from the content data stored in the memory of the successfully authenticated recording device 400. Specifically, this is executed as a process of extracting contents for which the content type (contained in the usage policy of the content data) indicates a program.

[0778] Then at step S653, information (such as the name of the program that can be activated and which has been extracted at step S652) is displayed on a display means. Although the display means is not shown in Fig. 2, AV output data are output to the display means (not shown). User provided information, such as a program name for each content data, is stored in the content ID of the content data. This is done so that program information (such as a program name for each authenticated content data) is output to the output means via the control section 301 that is under the control of the main CPU 106 shown in Fig. 2.

[0779] Then at step S654, the main CPU 106 receives the user's program selection input from the input means. The input means can be such as the input interface, controller, mouse, or keyboard shown in Fig. 2. Input occurs via the interface 110, —. At and at step S655, ~~executes~~ the user selected program is executed in accordance with the selection input.

[0780] As described above, in the data processing apparatus according to the present invention, the program activation priority is stored in the usage policy (which is in the header of the content data) so that the recording and reproducing device 300 activates programs in accordance with this priority. Alternatively, — or the display means can displays activated program information from which the user can selects a desired program. This configuration eliminates the need for the user to retrieve programs, ~~to~~ saving the amount of time and labor required for the activation. Additionally, the programs that

can be activated are activated after all the recording devices 400 have been authenticated or are shown to be such programs, ~~—~~. This ~~thereby eliminating—eliminates~~ the ~~complicatedness~~ complexity of the process, such as the need to validate a program after selection.

(15) Content Configuring and Reproducing (Decompressing) Process

[0781] In the data processing apparatus according to the present invention, the recording and reproducing device 300 downloads a—content from the medium 500 or the communication means 600, or reproduces data from the recording device 400, as described above. The above description focuses on the processing of encrypted data associated with the downloading or reproduction of a—content.

[0782] The control section 301 of the recording and reproducing device 300 in Fig. 3 generally controls the authentication, encryption, and decryption processes associated with the downloading or reproduction of content data from the device 500—~~such as a DVD which provides content data,~~ the communication means 600, or the recording device.

[0783] Reproducible contents resulting from these processes are, for example, sound data, ~~or~~ image data or the like. Decrypted data from the control section 301 ~~is~~ are placed under the control of the main CPU (shown in Fig. 2) and output to the AV output section, depending on the sound or image data—~~or~~ like. If, ~~however,~~ the content is, for example, sound data that ~~have~~ has been MP3-compressed, an MP3 decoder in the AV output section (shown in Fig. 2) decrypts and outputs the sound data. ~~In addition, if~~ If the content data are ~~includes~~ images that have been MPEG2-compressed, an MP2 decoder in the AV output section decompresses and outputs the image data. In this manner, the data contained in the content data may have or have not been compressed (encoded). ~~—, and are~~ The data is output after being processed depending on the content.

[0784] However, due to various types of compression and decompression process programs, even if the content provider provides compressed data, ~~these—this~~ data cannot be reproduced

without a corresponding decompression process executing program.

[0785] Thus, the present invention discloses a data processing apparatus wherein compressed data and a decryption (decompression) process program therefor are stored in a data content. ~~Or~~ Alternatively, link information for the compressed data and the decryption (decompression) process program therefor is stored as header information in the content data.

[0786] Fig. 60 is a view obtained by simplifying elements from the general view of data processing shown in Fig. 2, which relate to the present configuration. The recording and reproducing device 300 receives various contents from the device 500 (such as a DVD or a CD), the communication means 600, or the recording device 400 (such as a memory card, which stores ~~contents~~ content). ~~These~~ This contents can include various data such as sound data, still images, animated image data, and program data which ~~have~~ has or ~~have~~ has not been encrypted or compressed.

[0787] If the received content has been encrypted, the decryption process is executed using a method such as that described above and based on the control of the control section 301 and the cryptography process ~~by the~~ of cryptography process section 302. The decrypted data ~~are~~ is transferred to the AV process section 109 under the control of the CPU 106, where the data are stored in a memory 3090 of the AV process section 109. Then, a content analysis section 3091 analyzes the configuration of the content. If, for example, a data decompressing program is stored in the content, it is stored in a program storage section 3093. If, the content contains sound, ~~or~~ image data or the like, ~~this~~ these data are stored in a data storage section 3092. A decompression process section 3094 uses a decompression process program, such as MP3 (which is stored in the program storage section), to decompress compressed data stored in the data storage section 3092. The data ~~are~~ is then output to speakers 3001 or a monitor 3002.

[0788] Next, some examples of configurations of data received by the AV process section 109 (via the control section 301) and of relevant processes will be explained. Here,

sound data will be shown as an example of ~~a content, and a~~
Content with the MP3 applied thereto will be described as a
representative compression program. This configuration,
however, is applicable to image data as well as sound data,
~~and not only the MP3 decompression process program but also~~
other various such programs for MPEG2 or MPEG4 can be applied
thereto instead of MP3.

[0789] Fig. 61 shows an example of the configuration of a
content. This figure shows ~~music-sound~~ data 6102 compressed by
means of the MP3, and a MP3 decryption (decompression) process
program 6101, ~~which~~ Sound data 6102 and MP3 decryption
process program 6101 are integrated together into one content
block. Such contents blocks are each stored in the medium 500
or the recording device 400, and are distributed from the
communication means 600, as a single content block. If these
content blocks have been encrypted as previously described,
the recording and reproducing device 300 uses the cryptography
process section 303 to decrypt the content and then transfers
it to the AV process section 109.

[0790] The content analysis section 3091 of the AV process
section 109 analyzes the received content, takes a sound data
decompression program (MP3 decoder) section out from the
content, ~~comprising a sound data decompression program (MP3~~
~~decoder) section and a compressed sound data section, and~~
stores it in the program storage section 3093. The sound data
decompression program comprises a sound data decompression
program (MP3 decoder) section and a compressed sound data
section. ~~while storing~~ The compressed sound data is stored
in the data storage section 3092. The content analysis section
3091 may receive information such as a content name or content
configuration information in addition to the content, or it
may analyze the content based on identification data such as a
data name, or other data such as a data length or a data
configuration, which are all contained in the content. Then, a
compression and decompression process section 3094
decompresses the MP3-compressed sound data stored in the data
storage section 3092 in accordance with the sound data
decompression program (MP3 decoder) (stored in the program

storage section 3093). The AV process section 109 then outputs the decompressed sound data to the speakers 3001.

[0791] Fig. 62 shows ~~a flow showing~~ an example of a process for reproducing data of the content configuration in Fig. 61. At step S671, a data name stored in the memory 3090 of the AV process section 109, (for example, information such as the title of music present if the content is sound data) is taken out from the information received separately from the content, or from data in the content, and is then displayed on the monitor 3002. At step S672, the user's selection is received from one of the various input means, such as the switches and the keyboard via the input interface 110. ~~A, and a~~ reproduction process command, based on user input data, is then output to the AV process section 109, which is under the control of the CPU 106. At step S673, the AV process section 109 extract and decompress data selected by the user.

[0792] Next, Fig. 63 shows an example of a configuration wherein ~~a the~~ content contains either ~~the~~ compressed sound data or the decompression process program. ~~It and~~ also contains content information indicating what the content contains, such as header information for each content.

[0793] As shown in Fig. 63, if the content is a program 6202, the content contains as header information 6201, content identification information indicating that this is a program and that the type of program is to be MP3-decompressed. On the other hand, if sound data 6204 ~~are is~~ contained as a content, the content information in the header 6203 indicates that the data ~~have~~ has been MP3-compressed. This header information can be configured by selecting only information required for reproduction from the data contained in the usage policy (see Fig. 5). This is done as shown in the ~~above~~ above-described content data configuration-~~shown~~, for example, in Fig. 4. ~~and adding t~~ This information is added to the content transferred to the AV process section 109. Specifically, identification values for usage policy data, required for the cryptography process section 302 and for data required for the AV process section 109 during the reproduction process, are added to each constituent data of the "usage policy" shown in Fig. 5. ~~and~~

Only data indicating that these identification values are required for the AV process section 109 are extracted as header information.

[0794] On receiving each content block shown in Fig. 63, the content analysis section 3091 of the AV process section 109 stores, in accordance with the header information, a program content in the program storage section 3093, if the content is a program. Otherwise, it stores the program content ~~ex~~ in the data storage section 3092 if the content is data. Thereafter, the compression and decompression section 3094 takes the data out from the data storage section and decompresses ~~them~~ it in accordance with the MP3 program stored in the program storage section 3093. This is done before outputting the decompressed data. If the program storage section 3093 has the same program already stored therein, the program storage process may be omitted.

[0795] Fig. 64 shows an flow ~~showing an example of a~~ process for reproducing data of the content configuration in Fig. 63. At step S675, a data name ~~stored in the memory 3090 of the AV process section 109, for example, information such as the title of music present if the content is sound data~~ is taken out from the information received separately from the content or from the header in the content, and is then displayed on the monitor 3002. The data name, stored in the memory 3090 of the AV process section 109, is, for example, information such as the title of music (if the content is sound data). At step S676, the user's selection is received from one of the various input means, such as the switches and the keyboard, via the input interface 110.

[0796] Then at step S677, a data reproducing program (for example, the MP3,) corresponding to the user selection, is retrieved. The maximum range of this program retrieval is preferably set as the possible access range of the recording and reproducing device 300. ~~and~~ For example, the media 500, communication means 600, and recording device 400 shown in Fig. 60 are included in the retrieval range.

[0797] The ~~only the~~ content passed to the AV process section 109 is the data section. T, ~~while the program content~~

may be stored in another recording medium 500 in the recording and reproducing device 300. Alternatively, the program content may be—or provided by the content provider via the medium 500, such as a DVD or a CD. Accordingly, the retrieval range is set as the possible access range of the recording and reproducing device 300. When a reproduction program is found as a result of the retrieval, a reproduction process command, based on the user input data, is output to the AV process section 109 (under the control of the CPU 106). At step S679, the AV process section 109 extracts and decompress data depending on the user's selection. In another embodiment, the program retrieval is executed before step S675, so that only the data in which the program has been detected are displayed at step S675.

[0798] Next, Fig. 65 shows an example of a configuration wherein a—content contains compressed sound data 6303 and decompressed process program 6302, and further contains a content reproduction priority as header information 6301 therefor. This is an example of the above content configuration in Fig. 61 with the reproduction priority added thereto as header information. As in the above described section "(14) Program Activating Process Based on Activation Priority in Usage Policy in Content Data," the order of reproduction is determined based on a reproduction priority set among contents received by the AV process section 109.

[0799] Fig. 66 shows a—flow showing an example of a process for reproducing data of the content configuration in Fig. 65. At step S681, data stored in the memory 3090 of the AV process section 109, (that is, data information for data to be reproduced) is set in a retrieval list. The retrieval list is set using some areas of the memory in the AV process section 109. Then at step S682, the content analysis section 3091 of the AV process section 109 selects data of top priority. —and aAt step S683, it reproduces the selected data.

[0800] Next, Fig. 67 shows an example of a configuration wherein a—content comprises a combination of header information and program data 6402, or header information 6403

and compressed data 6404. ~~and wherein A~~ a reproduction priority is added only to the header 6403 of the data content.

[0801] Fig. 68 shows ~~a flow showing~~ an example of a process for reproducing data of the content configuration in Fig. 67. At step S691, data stored in the memory 3090 of the AV process section 109, (that is, data information for data to be reproduced) is set in a retrieval list. The retrieval list is set using some areas of the memory in the AV process section 109. Then at step S692, the content analysis section 3091 of the AV process section 109 selects data of top priority.

[0802] Then at step S693, a data reproducing program (for example, the MP3), corresponding to the user selection, is retrieved. As in the process in the flow in Fig. 64, the maximum range of this program retrieval is preferably set as the possible access range of the recording and reproducing device 300. ~~, and f~~For example, the media 500, communication means 600, and recording device 400 (shown in Fig. 60) are included in the retrieval range.

[0803] When a reproduction program is found as a result of the retrieval (Yes at step S694), the selected data ~~are~~ is decompressed and reproduced using the program obtained as a result of the retrieval.

[0804] On the other hand, if no program is found as a result of the retrieval (~~Yes~~ No at step S694), the process proceeds to step S696. ~~to Step 696 deletes those of the~~ remaining data contained in the retrieval list (set at step S691) that must be reproduced using the same program. This is because it is apparent that a new attempt to retrieve a reproduction program from these data fails. Furthermore, when it is determined whether or not the retrieval list is empty (and if the list is determined not to be empty), the process returns to step S692 to extract data of the next highest priority to execute the program retrieving process.

[0805] Thus, according to this configuration, if the compressed content is constructed with its decryption (decompression) program ~~or comprises only data obtained by compressing the content or only the decompression process program, since it has the header information indicating what~~

~~compressed data the content is or what process the content executes,~~ the process section (for example, the AV process section) receiving the content uses the decompression process program attached to the compressed data in order to execute the decompression and reproduction process. Alternatively, the process section ~~or~~ retrieves the decompression and reproduction program based on the header information in the compressed data to execute the decompression and reproduction process in accordance with the program obtained as a result of the retrieval. The compressed data can also comprise only data obtained by compressing the content or only the decompression process program, since it has the header information indicating what compressed data the content is or what process the content executes. This eliminates the needs for processes executed by the user, such as the selection and retrieval of the data decompressing program, ~~to reduce burdens on the user,~~ thereby enabling efficient data reproduction. Moreover, the configuration having with the reproduction priority in the header enables the reproduction order to be automatically set to allow the user to omit the operation of setting the reproduction order.

[0806] In the above described embodiments, the MP3 is taken as an example of a decompression process program for compressed sound data contents and sound compressed data, ~~but~~ this configuration is also applicable to contents containing compressed data, or a decompression process program for compressed image data, and provides similar effects in this other case.

(16) Generation of Save Data and Storage and Reproduction of the Same in and from Recording Device

[0807] If, for example, the content executed in the recording and reproducing device 300 is a game program or the like and if the game program is to be resumed a predetermined period of time after suspension, the state of the game is saved and the like at the time of the suspension are saved, ~~that is,~~ the state of the game is stored in the recording

device 400 so as to be read out on resumption, ~~to enable enabling~~ the game to be continued.

[0808] In conventional recording and reproducing devices 400 for game apparatuses, personal computers, or the like, a save data preservation configuration is provided with such a configuration. This as-to-preserved save data in a recording medium 500, such as a memory card, a floppy disk, a game cartridge, or a hard disk, which can be built into the recording and reproducing device 300 or externally attached thereto. In particular, however, these recording and reproducing devices 300 have no configuration for maintaining the security of the save data and carry out the save process using, for example, specifications common to a game application program.

[0809] Thus, for example, save data saved using a recording and reproducing device A may be used or rewritten by another game program; ~~However,~~ little attention has been paid to the security of the save data.

[0810] The data processing apparatus according to the present invention provides a configuration that can maintain the security of save data. For example, save data for a certain game program ~~are~~ is encrypted based on information used only by this game program before being stored in the recording device 400. Alternatively, the save data ~~are~~ is encrypted based on information unique to the recording and reproducing device 300 before being stored in the recording device 400. These methods enables the usage of the save data to be limited to particular apparatuses or programs to maintain the security of the data. "Generation of Save Data and Storage and Reproduction of the Same in and from Recording Device" in the present data processing apparatus will be explained below.

[0811] Fig. 69 is a block diagram ~~useful in explaining~~ illustrating a save data storage process in the present data processing apparatus. ~~A~~ eContent from the medium 500, such as a DVD or CD, or from the communication means 600, is provided to the recording and reproducing device 300. The provided content has been encrypted with the content key Kcon.

Kcon, which is a key unique to the content as described above, and The recording and reproducing device 300 obtains the content key in accordance with the process described in the above described section "(7) Process for Downloading from Recording and Reproducing Device to Recording device" (see Fig. 22), to decrypt the encrypted content, and then stores it in the recording device 400. The following description is directed to a process executed by the recording and reproducing device 300 to decrypt a content program from the medium 500 or the communication means 600. It reproduces and executes this program, and then stores the obtained save data in one of the various recording devices 400A, 400B, and 400B (such as external or built-in memory card and hard disk) for reproduction, ~~or Or to it downloads a content in the recording device 400A, reproduces and executes the content from the recording device 400A, and stores the resulting save data in a processing and recording device 400, for storing the save data in any one of the various recording devices 400A, 400B, and 400B (such as external or built-in memory card and hard disk for reproduction and reproducing the save data).~~

[0812] The recording and reproducing device 300 has the recording and reproducing device identifier IDdev, the system signature key Ksys (which is a signature key shared throughout the system), the recording and reproducing device signature key Kdev (which is unique to individual recording and reproducing devices), and the master keys for generating various individual keys, as previously described. The master keys are used to generate, for example, the distribution key Kdis or the authentication key Kake, as described in detail in "(12) Configuration for Generating Cryptography Process Keys Based on Master Keys." Here, the type of the master key is not particularly limited, but a key representing the master keys of the recording and reproducing device 300 is denoted by MKx. Fig. 69 shows an example of the cryptography key, Ksav, for save data in the lower part ~~thereof~~ of the figure. The save data cryptography key, Ksav, is used for the encryption process executed to store save data in one of the various recording device 400A to C, and for the decryption process

executed to reproduce these data therefrom. The processes for storing and reproducing save data will be explained with reference to Fig. 70 and subsequent figures.

[0813] Fig. 70 is a flow chart of a process of storing save data in one of the recording device 400A to C using either the content unique key or the system common key. The process in each flow is executed by the recording and reproducing device 300, ~~and~~ Tthe recording device 400 storing the save data in each flow may be any of the external recording devices 400A to C, ~~and~~ but is not limited to a particular one.

[0814] At step S701, the recording and reproducing device 300 reads out the content ID, for example, the game ID. This ID is the data contained in the identification information in the content data shown in the previously described Figs. 4, 26, 27, and 32 to 35. On receiving a command for storage of save data via the interface 110 (shown in Fig. 2), the main CPU 106 commands the control section 301 to read the content ID.

[0815] The control section 301 takes the identification information out from the header in the content data via the read section if the execution program is a ~~a~~content from a DVD, a CD-ROM, or the like (which is executed via the read section 304), or takes it out via the recording device controller 303 (if the execution program is a content stored in the recording device 400). If the recording and reproducing device 300 is executing the content program and the content ID has already been stored in a ~~a~~RAM or another accessible recording medium in the recording and reproducing device 300, the identification information contained in the loaded data may be used without executing a new read process.

[0816] Then at step S702, the process is changed depending on whether or not the program is to be localized. The program localization is used to set whether or not a limitation is added ~~which~~ that allows save data to be used only by this program, ~~—~~ Tto allow the save data to be used only by this program, "Program Localization" is set to "Yes.", ~~and~~ — tTo prevent the usage of the data from being limited to this program, "Program Localization" is set to "No." ~~—~~ This may be arbitrarily set by the user or may be set and stored in the

content program by the content producer. T, and the set localization is stored in one of the recording devices 400A to C (of Fig. 69) as a data managing file.

[0817] Fig. 71 shows an example of the data managing file. The data managing file is generated as a table. The table containing ~~contains~~ entries including data numbers, content IDs, recording and reproducing device IDs, and program localization. The content ID is identification data for a content program for which save data ~~are~~ is saved. The recording and reproducing device ID indicates a recording and reproducing device 300 that has stored the save data, ~~and~~ An example thereof is [IDdev], shown in Fig. 69. The program localization is set to "Yes" in order to allow the save data to be used only by this program, or to "No" in order to prevent the usage of the data from being limited to this program. The program localization may be arbitrarily set by the user using the content program, or may be set and stored in the content program by the content producer.

[0818] Referring back to Fig. 70, ~~the flow will be continuously explained.~~ If the program localization is set to "Yes" at step S702, the process proceeds to step S703. At step 703, the key unique to the content, for example, the content key Kcon, is read out from the content data and used as the save data cryptography key Ksav, ~~or~~ Otherwise, the save data cryptography key, Ksav, is generated based on the content unique key.

[0819] On the other hand, if the program localization is set to "No" at step S702, the process proceeds to step S707. At step 707, the system common key stored in the recording and reproducing device 300, (for example, the system signature key), Ksys is read out from the internal memory 307 of the recording and reproducing device 300 and is used as the save data cryptography key Ksav, Otherwise, ~~or~~ the save data cryptography key, Ksav, is generated based on the system signature key Ksys. Alternatively, a cryptography key different from the other keys (which have ~~has~~ been separately saved to the internal memory 307 of the recording and

reproducing device 300) may be used as the save data cryptography key Ksav.

[0820] Then at step S704, the save data cryptography Ksav selected or generated at step S703 or S707, is used to execute a process for encrypting save data. This encryption process is executed by the cryptography process section 302 ~~of~~ (see Fig. 2) by applying, for example, the above described DES algorithm.

[0821] The save data encrypted at step S704 ~~are~~ is stored in the recording device at step S705. If there are a plurality of recording devices 400 that can store save data, (as shown in Fig. 69), the user selects ~~in advance~~ one of the recording devices 400A to C in advance as a save data storage destination. Further, at step S706, the program localization set at step S702, (that is, "Yes" or "No" for the program localization) is written to the data managing file described with reference to Fig. 71.

[0822] The process for storing the save data is thus completed. At step S702, save data for which "Yes" is selected for the program localization at step S702, and which are encrypted at step S703 with the save data encryption key Ksav (generated based on the content unique key) ~~are~~ is prevented from being decrypted by content programs having no content unique key information. ~~, so that~~ Thus, these save data can be used only by content programs having the same content key information. In this case, however, the save data encryption key Ksav is not generated based on information unique to the recording and reproducing device 300, so that save data stored in a removable recording device 400 (such as a memory card) can be reproduced even from a different recording and reproducing device 300, as long as they are used together with a corresponding content program.

[0823] Additionally, save data for which "No" is selected for the program localization at step S702 (and which are encrypted at step S707 with the save data encryption key Ksav) ~~based on the system common key~~ can be reproduced and used, even if a program with a different content identifier is used, or if a different recording and reproducing device 300 is used.

[0824] Fig. 72 ~~shows a flow showing~~ illustrates a process for reproducing save data stored by means of the save data storage process in Fig. 20.

[0825] At step S711, the recording and reproducing device 300 reads out the content ID, for example, the game ID. This is a process similar to step S701 ~~of the~~ previously described in Fig. 70, and which reads out data contained in the identification information ~~in of~~ the content data.

[0826] Then at step S712, the data managing file (described with reference to Fig. 71) is read out from one of the recording devices 400A to C (shown in Fig. 69, ~~and the~~ The content ID (read out at step S711) and correspondingly set program localization are extracted therefrom. In step S713, if the data managing file has the program localization set to "Yes," the process proceeds to step S714, ~~whereas.~~ If the data managing file has the program localization set to "No," the process advances to step S717.

[0827] At step S714, the key unique to the content, (for example, the content key Kcon) is read out from the content data and is used as the save data decryption key Ksav, ~~Oer,~~ the save data decryption key Ksav is generated based on the content unique key. This decryption key generating process uses a process algorithm corresponding to the encryption key generating process, ~~T~~ that is, a decryption key generating algorithm that enables data encrypted based on a certain content unique key to be decrypted with a decryption key generated based on the same content unique key.

[0828] On the other hand, if it is determined at step ~~S712~~ S713 that the data managing file has the program localization set to "No," ~~then at step S717,~~ the system common key (stored in the recording and reproducing device 300, ~~for example, the system signature key Ksys~~ is read out from the internal memory 307 of the recording and reproducing device 300 and is used as the save data decryption key Ksav, ~~Oer,~~ the save data decryption key Ksav is generated based on the system signature key Ksys. Alternatively, a cryptography key different from the other keys ~~which has~~ that have been separately saved to the

internal memory 307 of the recording and reproducing device 300 may be used as the save data cryptography key Ksav.

[0829] Then at step S715, the save data decryption key Ksav, selected or generated at step S714 or S717, is used to execute a process for decrypting save data, ~~and~~ at step S716, the decrypted save data ~~are~~ is reproduced and executed in the recording and reproducing device 300.

[0830] The save data reproduction process is thus completed. As described above, the save data decryption key is generated based on the content unique key if the data managing file has the program localization set to "Yes," ~~while otherwise,~~ the save data decryption key is generated based on the system common key if the data managing file has the program localization set to "No." If the program localization is set to "Yes," a decryption key cannot decrypt the save data without the same content ID for the content, thereby enabling the security of the save data to be improved.

[0831] Figs. 73 and 74 show save data storage and reproduction flows, respectively, that generate save data encryption and decryption keys using the content ID.

[0832] In Fig. 73, steps S721 to S722 are similar to steps S701 and S702 in Fig. 70, so description thereof is omitted.

[0833] ~~The save data storage flow in Fig. 73, if~~ If the program localization is set to "Yes" at step S722, then at step S723, the content ID is read out from the content data and is used as the save data decryption key Ksav, or the save data decryption key Ksav is generated based on the content ID. For example, the cryptography process section 307 of the recording and reproducing device 300 can apply the master key MKx (stored in the internal memory of the recording and reproducing device 300), to the content ID read out from the content data, ~~—~~. This is done to obtain the save data decryption key Ksav that is based, for example, on the DES (MKx, content ID). Alternatively, a cryptography key different from the other keys (which has ~~have~~ been separately saved to the internal memory 307 of the recording and reproducing device 300) may be used as the save data decryption key Ksav.

[0834] On the other hand, if the program localization is set to "No" at step S722, then at step S727, the system common key stored in the recording and reproducing device 300, (for example, the system signature key Ksys) is read out from the content data and is used as the save data encryption key Ksav, or the save data encryption key Ksav is generated based on the system signature key. Alternatively, a cryptography key different from the other keys (~~which has~~ have been separately saved to the internal memory 307 of the recording and reproducing device 300) may be used as the save data decryption key Ksav.

[0835] The processing at step S724 and the subsequent steps is similar to that at step S704 and the subsequent steps in the process flow in ~~the above-described~~ Fig. 70, and description thereof is thus omitted.

[0836] ~~Further,~~ Fig. 74 shows a process flow for reproducing and executing save data stored in the recording device 400 during the save data storage process flow in Fig. 73, ~~and~~ sSteps S731 to S733 are similar to the corresponding processing in the ~~above~~—described Fig. 72, except for step S734. At step 734, the content ID is read out from the content data and is used as the save data decryption key Ksav, or the save data decryption key, Ksav is generated based on the content ID. This decryption key generating process uses a process algorithm corresponding to the encryption key generating process, ~~—~~. Tthat is, a decryption key generating algorithm that enables data encrypted based on a certain content ID to be decrypted with a decryption key generated based on the same content ID.

[0837] The subsequent processing, steps S735, S736, and S737 are similar to the corresponding processing in Fig. 72, and description thereof is thus omitted. According to the save data storage and reproduction processes in Figs. 73 and 74, if the program localization is set to "Yes," ~~—~~ the content ID is used to generate the save data encryption and decryption keys, so that as in the above save data storage and reproduction processes using the content unique key, save data cannot be

obtained without matching the corresponding content program, thereby enabling save data to be saved more securely.

[0838] Figs. 75 and 77 show save data storage (Fig. 75) and reproduction (Fig. 77) flows, respectively, that generate save data encryption and decryption keys using the recording and reproducing device unique key.

[0839] In Fig. 75, step S741 is similar to step S701 in Fig. 70, so description thereof is omitted. At step S742, localization is or is not set for the recording and reproducing device 300. In the case of localizing a particular recording and reproducing device 300 capable of utilizing the save data, a recording and reproducing device localization, ~~that is, allows the save data to be used only by the recording and reproducing device that has generated and stored the data, the recording and reproducing device localization is set to "Yes."~~ That is, the save data is allowed to be used only by the recording and reproducing device that has generated and stored the data. ~~To allow other recording and reproducing device to use the save data, the recording and reproducing device localization is set to "No."~~ If the recording and reproducing device localization is set to "Yes" at step S742, the process proceeds to step S743, and if this localization is set to "No," the process proceeds to step S747.

[0840] An example of the data managing file is shown in Fig. 76. The data managing file is generated as a table. The table containing contains entries including data numbers, content IDs, recording and reproducing device IDs, and recording and reproducing device localization. The content ID is identification data for a content program for which save data ~~is~~ saved. The recording and reproducing device ID indicates a recording and reproducing device 300 that has stored the save data. ~~, and an~~ An example thereof is [IDdev], shown in Fig. 69. The recording and reproducing device localization is set to "Yes" in order to limit the usage of the save data to a particular recording and reproducing device 300. ~~, that is, allow the save data is allowed to be used only by the recording and reproducing device that has generated and stored~~

the data~~—~~. Recording and reproducing device localization is set ~~or~~ to "No" in order to allow other recording and reproducing devices 300 to use the save data. The recording and reproducing device localization may be arbitrarily set by the user using the content program~~—~~, or may be set and stored in the content program by the content producer.

[0841] In the save data storage process flow in Fig. 75, if the recording and reproducing device localization is set to "Yes" at step S742, the recording and reproducing device unique key~~—~~ (for example, the recording and reproducing device signature key~~—~~, Kdev) is read out from the internal memory 307 of the recording and reproducing device 300 data~~—~~, and is used as the save data encryption key~~—~~, Ksav, or the save data encryption key Ksav is generated based on the recording and reproducing device signature key Kdev. Alternatively, a cryptography key~~—~~, different from the other keys which has been separately saved to the internal memory 307 of the recording and reproducing device 300~~—~~, may be used as the save data decryption key Ksav.

[0842] On the other hand, if the recording and reproducing device localization is set to "No" at step S742, then at step S747~~—~~, the system common key (stored in the recording and reproducing device 300~~—~~, ~~—~~for example, the system signature key Ksys) is read out from internal memory 307 of the recording and reproducing device 300 and used as the save data encryption key Ksav, or the save data encryption key Ksav is generated based on the system signature key. Alternatively, a cryptography key~~—~~, different from the other keys which has been separately saved to the internal memory 307 of the recording and reproducing device 300~~—~~, may be used as the save data decryption key Ksav.

[0843] The processing at steps S744 and S745 is similar to the corresponding processing in the process flow in ~~the above described~~ Fig. 72, and description thereof is thus omitted.

[0844] At step S746, the content ID, the recording and reproducing device ID, and the recording and reproducing device localization "Yes/No" (set by the user at step S742) are written to the data managing file (see Fig. 76).

[0845] Furthermore, Fig. 77 shows a process flow for reproducing and executing save data stored in the recording device 400 during the save data storage process flow in Fig. 75. At step S751, the content ID is read out as in the corresponding processing in the above described in relation to Fig. 72. Then at step S752, the recording and reproducing device ID (IDdev) stored in the memory of the recording and reproducing device 300 is read out.

[0846] At step S753, the content ID, the recording and reproducing device ID, and the set recording and reproducing device localization "Yes/No" are read out from the data managing file (see Fig. 76). If any entry in the data managing file (which has the same content ID) has the recording and reproducing device localization set to "Yes," the process is ended if the table entry has a recording and reproducing device ID different from that read out at step S752.

[0847] Next, if it is determined at step S754 that the data managing file has the recording and reproducing device localization set to "Yes," the process proceeds to step S755. ~~If~~ ~~whereas~~ ~~if~~ the data managing file has the recording and reproducing device localization set to "No," the process proceeds to step S758.

[0848] At step S755, the recording and reproducing device unique key (for example, the recording and reproducing device signature key Kdev) is read out from the internal memory 307 of the recording and reproducing device 300 data and is used as the save data decryption key Ksav. ~~or~~ ~~or~~ Or, the save data encryption key Ksav is generated based on the recording and reproducing device signature key Kdev. This decryption key generating process uses a process algorithm corresponding to the encryption key generating process. Tthat is, a decryption key generating algorithm is used that enables data encrypted based on a certain recording and reproducing device unique key to be decrypted with a decryption key (that was generated based on the same recording and reproducing device unique key). Alternatively, a cryptography key, different from the other keys, which has been separately saved to the

internal memory 307 of the recording and reproducing device 300, may be used as the save data decryption key Ksav.

[0849] On the other hand, at step S758, the system common key stored in the recording and reproducing device 300, (for example, the system signature key Ksys) is read out from internal memory 307 of the recording and reproducing device 300 and used as the save data decryption key Ksav. Or, the save data decryption key Ksav is generated based on the system signature key. Alternatively, a cryptography key different from the other keys (which has been separately saved to the internal memory 307 of the recording and reproducing device 300) may be used as the save data decryption key Ksav. The processing at the subsequent steps S756 and S757 are similar to that at the corresponding steps in the above described save data reproduction process flow.

[0850] According to the save data storage and reproduction process flows shown in Figs. 75 and 77, save data for which the recording and reproducing device localization is set to "Yes" ~~are~~ is encrypted and decrypted using the recording and reproducing device unique key. ~~These~~ This save data can thus be decrypted and used only by the recording and reproducing device 300 having the same recording and reproducing device unique key, ~~that is i.e.~~, the same recording and reproducing device 300.

[0851] Next, Figs. 78 and 79 show process flows for generating encryption and decryption keys for save data using the recording and reproducing device ID and storing and reproducing the save data.

[0852] In Fig. 78, the recording and reproducing device ID is used to encrypt and store save data in the recording device 400. Steps S761 to S763 are similar to those in the above Fig. 75. At step S764, the recording and reproducing device ID (IDdev), read out from the recording and reproducing device, is used to generate the save data encryption key Ksav. The save data encryption key Ksav is obtained based on the IDdev. This is done by, for example, applying the IDdev as the save data encryption key Ksav, or applying the master key MKx (stored in the internal memory of the recording and

reproducing device 300) to obtain the save data encryption key Ksav based on the DES (MKx, IDdev). Alternatively, a cryptography key different from the other keys which ~~has~~have been separately saved to the internal memory 307 of the recording and reproducing device 300, may be used as the save data decryption key Ksav.

[0853] The subsequent process steps S765 to S768 are similar to the corresponding processing in the above described Fig. 75, so description thereof is omitted.

[0854] Fig. 79 shows a process flow for reproducing and executing the save data stored in the recording device 400 by means of the process in Fig. 78. Steps S771 to S774 are similar to the corresponding processing in ~~the above described~~ Fig. 77.

[0855] At step S775, the recording and reproducing device ID (Iddev), read out from the recording and reproducing device, is used to generate the save data decryption key Ksav. The save data encryption key Ksav is obtained based on the Iddev. This is performed by, for example, applying the IDdev as this key Ksav, or applying the master key MKx (stored in the internal memory of the recording and reproducing device 300) to obtain this key Ksav based on the DES (MKx, IDdev). This decryption key generating process uses a process algorithm corresponding to the encryption key generating process, ~~—~~. T~~t~~hat is, a decryption key generating algorithm that enables data encrypted based on a certain recording and reproducing device unique key to be decrypted with a decryption key generated based on the same recording and reproducing device unique key. Alternatively, a cryptography key, different from the other keys which has been separately saved to the internal memory 307 of the recording and reproducing device 300, may be used as the save data decryption key Ksav.

[0856] The subsequent process steps S776 to S778 are similar to the corresponding processing in the above described Fig. 76.

[0857] According to the save data storage and reproduction process flows shown in Figs. 78 and 79, save data for which the recording and reproducing device localization is set to

"Yes" ~~are~~is encrypted and decrypted using the recording and reproducing device unique key. ~~These~~This save data can thus be decrypted and used only by the recording and reproducing device 300 having the same recording and reproducing device unique key, that is, the same recording and reproducing device 300.

[0858] Next, save data storage and reproduction processes of executing both the above described program localization and recording and reproducing device localization will be explained with reference to Figs. 80 to 82.

[0859] Fig. 80 shows a save data storage process flow. At step S781, the content ID is read out from the content data, at step S782, it is determined whether the program localization is set, and at step S783, it is determined whether the recording and reproducing device localization is set.

[0860] If both the program localization and the recording and reproducing device localization are set to "Yes", then at step S785, the save data encryption key Ksav is generated based on both the content unique key (ex. Kcon) and the recording and reproducing device unique key (Kdev). The save data encryption key is obtained, for example, based on $Ksav = (Kcon \text{ XOR } Kdev)$ or by applying the master key MKx (stored in the internal memory of the recording and reproducing device 300) to obtain this key based on $Ksave = DES (MKx, Kcon \text{ XOR } Kdev)$. Alternatively, a cryptography key, different from the other keys which ~~has~~have been separately saved to the internal memory 307 of the recording and reproducing device 300, may be used as the save data decryption key Ksav.

[0861] If the program localization is set to "Yes" while the recording and reproducing device localization is set to "No", then at step S786, the content unique key (ex. Kcon) is used as the save data encryption key Ksav, ~~or~~Or, the save data encryption key Ksav is generated based on the content unique key (ex. Kcon).

[0862] If the program localization is set to "No" while the recording and reproducing device localization is set to "Yes", then at step S787, the recording and reproducing device unique

key (Kdev) is used as the save data encryption key Ksav~~—~~. ~~Or,~~ the save data encryption key Ksav is generated based on the recording and reproducing device unique key (Kdev). Alternatively, a cryptography key, different from the other keys (which has—have been separately saved to the internal memory 307 of the recording and reproducing device 300), may be used as the save data decryption key Ksav.

[0863] Further, if both the program localization and the recording and reproducing device localization are set to "No," then at step S787, the system common key~~—~~ (for example, the system signature key Ksys) is used as the save data encryption key Ksav~~—~~. ~~or—Or,~~ the save data encryption key Ksav is generated based on the system signature key Ksys. Alternatively, a cryptography key, different from the other keys (which has been separately saved to the internal memory 307 of the recording and reproducing device 300), may be used as the save data decryption key Ksav.

[0864] At step S789, the save data encryption key Ksav generated at one of the steps S785 to S788~~—~~, is used to encrypt the save data, which ~~are—~~is then stored in the recording device 400.

[0865] Furthermore, at step S790, the localization (set at steps S782 and S783) is stored in the data managing file. The data managing file is configured, for example, as shown in Fig. 81~~—~~, and contains entries including data numbers, content IDs, recording and reproducing device IDs, program localization, and recording and reproducing device localization.

[0866] Fig. 82A~~—~~and~~—~~82B shows a process flow for reproducing and executing the save data stored in the recording device 400 by means of the process in Fig. 80. At step S791, the content ID and the recording and reproducing device ID are read out from the execution program~~—~~. ~~And—~~at step S792, the content ID, the recording and reproducing device ID, the program localization, and the recording and reproducing device localization are read out from the data managing file shown in Fig. 81. In this case, if the program localization is set to "Yes" and the content IDs are not the same~~—~~, or if the recording and reproducing device localization

is set to "Yes" and the recording and reproducing device IDs are not the same, the process is ended.

[0867] Then at steps S793, S794, and S795, the decryption key generating process is set to one of the four manners at steps 796 to S799 in accordance with the data recorded in the data managing file.

[0868] If both the program localization and the recording and reproducing device localization are set to "Yes," then at step S796, the save data encryption key Ksav is generated based on both the content unique key (ex. Kcon) and the recording and reproducing device unique key (Kdev). Alternatively, a cryptography key different from the other keys (which ~~has~~ have been separately saved to the internal memory 307 of the recording and reproducing device 300) may be used as the save data decryption key Ksav. If the program localization is set to "Yes" while the recording and reproducing device localization is set to "No," then at step S797, the content unique key (ex. Kcon) is used as the save data encryption key Ksav. ~~Or,~~ Or, the save data encryption key Ksav is generated based on the content unique key (ex. Kcon). Alternatively, a cryptography key different from the other keys (which ~~has~~ have been separately saved to the internal memory 307 of the recording and reproducing device 300) may be used as the save data decryption key Ksav.

[0869] If the program localization is set to "No" while the recording and reproducing device localization is set to "Yes," then at step S798, the recording and reproducing device unique key (Kdev) is used as the save data encryption key Ksav. ~~Or,~~ Or, the save data encryption key Ksav is generated based on the recording and reproducing device unique key (Kdev). Alternatively, a cryptography key different from the other keys (which ~~has~~ have been separately saved to the internal memory 307 of the recording and reproducing device 300) may be used as the save data decryption key Ksav. Further, if both the program localization and the recording and reproducing device localization are set to "No," then at step S799, the system common key (for example, the system signature key Ksys) is used as the save data encryption key Ksav. ~~Or,~~ Or, the

save data encryption key Ksav is generated based on the system signature key Ksys. Alternatively, a cryptography key different from the other keys ~~(which has~~have been separately saved to the internal memory 307 of the recording and reproducing device 300) may be used as the save data decryption key Ksav.

[0870] These decryption key generating processes uses a process algorithm corresponding to the encryption key generating process~~r~~. ~~T~~that is, a decryption key generating algorithm that enables data encrypted based on the same content unique key and recording and reproducing device unique key to be decrypted with a decryption key generated based on the same content unique key and recording and reproducing device unique key.

[0871] At step S800, the save data encryption key Ksav, generated at one of the steps S796 to S799, is used to execute the decryption process~~r~~. ~~and~~~~t~~The decrypted save data are reproduced and executed in the recording and reproducing device 300.

[0872] According to the save data storage and reproduction process flows shown in Figs. 80 and 82, save data for which "Yes" is selected for the program localization ~~are~~is encrypted and decrypted with the content unique key~~r~~. ~~so that these~~This save data can be decrypted and used only if content data having the same content unique key ~~are~~is used. Additionally, save data for which "Yes" is selected for the recording and reproducing device localization ~~are~~is encrypted and decrypted with the recording and reproducing device ID, ~~so that these~~. This save data can be decrypted and used only by the recording and reproducing device having the same recording and reproducing device ID, that is, the same recording and reproducing device. Consequently, both the content and the recording and reproducing device can set the localization to further improve the security of the save data.

[0873] Although Figs. 80 and 82 show the configuration for generating the save data encryption key and the decryption key using the content unique key and the recording and reproducing device unique key, the content ID and the recording and

reproducing device ID may be used instead of the content unique key and the recording and reproducing device unique key, respectively, to generate the save data encryption key and the decryption key based on these IDs.

[0874] Next, a configuration for generating an encryption and a decryption keys, based on a password input by the user, will be described with reference to Figs. 83 to 85.

[0875] Fig. 83 shows a process flow for generating a save data encryption key based on a password input by the user and storing save data in the recording device.

[0876] At step S821, the content ID is read out from the content data as in each of the above described processes. At step S822, the user determines whether to set the program localization. The data managing file set in this configuration has, for example, the configuration shown in Fig. 84.

[0877] As shown in Fig. 84, the data contains data numbers, content IDs, recording and reproducing device IDs, and user set program localization. The "user set program localization" is an entry that determines whether or not the usage of the program is limited to a particular user.

[0878] If the localization is set to "Yes" at step S822 in the process flow in Fig. 83, then at step S823, the user's password is input. The password is input from an input means such as the keyboard shown in Fig. 2.

[0879] The input password is output to the cryptography process section 302 (under the control of the main CPU 106 and the control section 301), and the processing at step S824 is executed. That is, the save data encryption key Ksav is generated based on the input user password. The save data encryption key Ksav may be generated by, for example, setting the password itself as this key Ksav or using the master key MKx of the recording and reproducing device to generate this key Ksav based on the save data encryption key Ksav = DES (MKx, password). Alternatively, a unidirectional function may be applied, using the password as an input, so that an encryption key can be generated based on an output from the function.

[0880] If the user localization is set to "No" at step S822, then at step S828, a save data encryption key is generated

based on the system common key of the recording and reproducing device 300.

[0881] Further, at step S825, the save data encryption key Ksav (generated at step S824 or S828) is used to encrypt the save data, and at step S826, the encrypted save data ~~are~~ is stored in the recording device 400.

[0882] ~~Furthermore, a~~At step S827, the program localization set by the user at step S822 is written to the data managing file in Fig. 84, so as to be associated with the content ID and the recording and reproducing device ID.

[0883] Fig. 85 ~~is a view showing a flow of~~ illustrates a process for reproducing the save data stored by means of the process in Fig. 83. At step S831, the content ID is read out from the content data, ~~and a~~At step S832, the content ID and the program localization set by the user are read out from the data managing file shown in Fig. 84.

[0884] At step S833, determination is made based on the data in the data managing file. If "the user set program localization" is set to "Yes," ~~then~~ at step S834, the user is prompted to input a password, ~~and~~ Then at step S835, a decryption key is generated based on the input password. This decryption key generating process uses a process algorithm corresponding to the encryption key generating process, ~~that is,~~ a decryption key generating algorithm is used that enables data encrypted based on a certain password to be decrypted with a decryption key generated based on the same password.

[0885] If it is determined at step S833 that the program localization by the user is set to "No," ~~then~~ at step S837, the system common key stored in the internal memory of the recording and reproducing device 300 is used to generate the save data decryption key Ksav by using the system signature key Ksys. Alternatively, an encryption key, different from the other keys which ~~has~~ have been separately saved to the internal memory 307 of the recording and reproducing device 300, may be used as the save data encryption key Ksav.

[0886] At step S836, the decryption key Ksav (generated at step S835 or S837) is used to decrypt the save data stored in

the recording device~~7~~. ~~and a~~At step ~~S836~~S838, the recording and reproducing device 300 reproduces and executes the save data.

[0887] According to the save data storage and reproduction process flows shown in Figs. 83 and 85, save data for which "Yes" is selected for "the user set program localization" ~~are~~ is encrypted and decrypted with the key based on the user input password,. This is done so that ~~these~~this save data can be decrypted and used only if the same password is input, thereby improving the security of the save data.

[0888] The several aspects of the save data storage and reproduction processes have been described, but it is also possible to implement a process obtained by merging the above described processes together~~,~~. For example, an aspect of generating save data encryption and decryption keys may be performed using an arbitrary combination of the password, the recording and reproducing device ID, the content ID, and ~~others~~ information.

(17) Configuration for Excluding (Revoking) Invalid Apparatuses

[0889] As described above, the data processing apparatus according to the present invention improves the security of provided contents and allow such contents to be used only by valid users~~,~~. It usesing the configuration wherein the recording and reproducing device 300 executes processes such as authentication and encryption on various content data provided by the medium 500 (see Fig. 3), or the communication means 600, and then stores the data in the recording device 400.

[0890] As understood from the above description, the input content is authenticated, encrypted, and decrypted using the various signature keys, master keys, and integrity-check-value-generating keys (see Fig. 18) that are stored in the internal memory 307 (which is configured in the cryptography process section 302 of the recording and reproducing device 300). The internal memory 307 storing the key information is desirably characterized to restrain external illegal reads. ~~in that it~~It comprises a semiconductor chip that essentially

rejects external accesses and has a multilayer structure, an internal memory sandwiched between dummy layers of aluminum or the like or arranged in the lowest layer, and a narrow range of operating voltages and/or frequencies. If, however, these key data or the like should be read out from the internal memory 307 and copied to an unauthorized recording and reproducing device 300, the copied key information may be used for invalid usage of the content.

[0891] A configuration for preventing the invalid use of a content, based on invalid copying of a key, will be described below.

[0892] Fig. 86 is a block diagram ~~useful in explaining~~ illustrating "(17) Configuration for Excluding Invalid Apparatuses," which corresponds to this configuration. The recording and reproducing device 300 is similar to the recording and reproducing device 300 shown in ~~the above described Figs. 2 and 3.~~ It ~~and~~ has an internal memory, and the previously described various key data (Fig. 18) and recording and reproducing device ID. Here, the recording and reproducing device ID, the key data, or the like, copied by a third person, is not necessarily stored in the internal memory 307, ~~but~~ the The key data or the like in the recording and reproducing device 300 shown in Fig. 86 are collectively or distributively stored in a memory section accessible to the cryptography process section 302 (see Figs. 2 and 3).

[0893] To implement the configuration for excluding invalid apparatuses, a list of invalid recording and reproducing device IDs is stored in the header section of the content data. As shown in Fig. 86, the content data holds a ~~list of~~ revocation list as the list of invalid recording and reproducing device IDs (IDdev). Further, a list integrity check value ICVrev is used to check the revocation list for tampering. The list of invalid recording and reproducing device IDs (IDdev) contains the identifiers ~~IDdev~~ IDdev of invalid recording and reproducing devices 300, determined by the content provider or manager, based on the state of distribution of invalid copies or the like. The revocation list may be encrypted with the distribution key Kdis before

being stored. The decryption process executed by the recording and reproducing device 300 is similar to, for example, that in the content download process in ~~the above~~ Fig. 22.

[0894] Here, for better understanding, the revocation list is shown as single data in the content data, ~~in Fig. 86~~ but may be contained, for example, in the previously described usage policy (for example, see Figs. 32 to 35), which is a component of the header section of the content data. In this case, the previously described integrity check value ICVa is used to check the usage policy data containing the revocation list for tampering. If the revocation list is contained in the usage policy, the integrity check value $A\div$, ICVa, is used for the check, and the integrity-check-value-A-generating key, ~~Kicva~~ Kicva, in the recording and reproducing device 300 is used, thereby eliminating the need to store the integrity-check-value-generating key Kicv-rev.

[0895] If the revocation list is contained in the content data as independent data, the revocation list is checked using the list integrity check value ICVrev (for checking the revocation list for tampering), and an intermediate integrity check value is generated from the list integrity check value ICVrev and another partial integrity check value in the content data, and is used to carry out a verification process.

[0896] A method for checking the revocation list using the list integrity check value ICVrev for checking the revocation list for tampering is similar to the process for generating the integrity check value such as ICVa or ICVb as explained in the ~~above~~ above-described Figs. 23 and 24. That is, the calculation is executed in accordance with the ICV calculation method described in Figs. 23 and 24 and other figures, ~~—~~. The ~~using as a key used is~~ the integrity-check-value-generating key, Kicv-rev (stored in the internal memory 307 of the recording and reproducing device cryptography process section 302), and using ~~as a message~~ the revocation list contained in the content data as a message. The calculated integrity check value ICV-rev' and the integrity check value \div ICV-rev (stored in the header), are compared together, ~~—~~. If and if they are

equal, it is determined that the list ~~has~~ve not been tampered with.

[0897] The intermediate integrity check value, containing the list integrity check value ICVrev, is generated, for example, by using ~~as a key~~ the total-integrity-check-value-generating key Kicvt as a key. Kicvt is stored in the internal memory 307 of the recording and reproducing device cryptography process section 302. ~~and applying t~~The ICV calculation method described in Fig. 7 and other figures is applied to a message string comprising the integrity check values A and B and list integrity check value ICVrev in the verified header, ~~with~~. The content integrity check value is added thereto depending on the format, as shown in Fig. 25.

[0898] The revocation list and the list integrity check value are provided to the recording and reproducing device 300 via the medium 500 (such as a DVD or a CD), or the communication means 600, or via the recording device 400 (such as a memory card). In this case, the recording and reproducing device 300 may hold valid key data or illegally copied IDs.

[0899] Figs. 87 and 88 ~~show a flow of~~illustrate a process for excluding invalid recording and reproducing devices 300 in this configuration. Fig. 87 shows ~~a flow of~~ a process for excluding (revoking) invalid recording and reproducing devices 300 if ~~a content~~ is provided by the medium 500 (such as a DVD or a CD) or the communication means 600, ~~while~~. Fig. 88 shows ~~a flow of~~ a process for excluding (revoking) invalid recording and reproducing devices 300 if ~~a content~~ is provided by the recording device 400 (such as a memory card).

[0900] First, the process flow in Fig. 87 will be explained. At step S901, the medium 500 is installed and a request is made for ~~a content~~, that is, a reproduction or download process. The process shown in Fig. 87 corresponds to a step executed, for example, before installation of the medium 500 (such as DVD or the like) in the recording device 400, followed by the download process. The download process is as previously described with reference to Fig. 22 and is executed as a step before the process flow in Fig. 22 or as a process inserted into this process flow.

[0901] If the recording and reproducing device 300 receives ~~a~~ content via the communication means 600 (such as a network), then at step S911, a communication session with a content distribution service side is established, ~~and~~. The process then proceeds to step S902.

[0902] At step S902, the revocation list (see Fig. 86) is obtained from the header section of the content data. In this list ~~obtaining~~ process, if the content is present in the medium 500, the control section 301 (shown in Fig. 3) reads it out therefrom via the read section 304. If the content is obtained from the control section, the communication means ~~301~~ 600 shown in Fig. 3 receives it from the content distributing side via the communication section 305.

[0903] Next, at step S903, the control section 301 passes the revocation list (obtained from the medium 500 or the communication means 600), to the cryptography process section 302, ~~which~~. Cryptography process section 302 is then caused to execute the check value generating process. The recording and reproducing device 300 internally has the revocation-integrity-check-value-generating key Kicv-rev, ~~It~~ calculates the integrity check value ICV-rev' in accordance with the ICV calculation method described in Figs. 23 and 24 and other figures, ~~This is performed by applying the integrity-check-value-generating key Kicv-rev, using the received revocation list as a message, and~~. It compares the result of the calculation with the integrity check value ~~+~~, ICV-rev (stored in the header). If they are equal, ~~to it~~ determines that the list have ~~has not been tampered with if they are equal~~ (Yes at step S904). If the values are not equal, the recording and reproducing device determines that the list has been tampered with. In that case, and the process proceeds to step S909 to indicate a process error to end the process.

[0904] ~~Then a~~ At step S905, the control section 306 of the recording and reproducing device cryptography process section 302 causes the encryption/decryption section 308 of the recording and reproducing device cryptography process section 302 to calculate the total integrity check value ICVt'. The total integrity check value ICVt' is generated by using ~~as a~~

~~key~~ the system signature key Ksys as a key. Ksys is stored in the internal memory 307 of the recording and reproducing device cryptography process section 302. ~~and encrypting~~ The intermediate integrity check value is encrypted based on the DES, as shown in Fig. 25. The verification process, with each partial integrity check value such as the ICVa or ICVb, is omitted from the process flow shown in Fig. 87, ~~but~~ V verification with these partial check values is carried out depending on the data format as in the process flow in the previously described Figs. 39 to 45.

[0905] Then at step S906, the generated total integrity check value ICVt' is compared with the integrity check value ICVt in the header, ~~and~~. I if they are equal (Yes at step S906), the process advances to step S907. If the values are not equal, the recording and reproducing device determines that the list has been tampered with, and the process proceeds to step S909 to indicate a process error to end the process.

[0906] As previously described, the total integrity check value ICVt is used to check all the partial integrity check value contained in the content data, such as the ICVa and ICVb and integrity check values for corresponding content blocks, which are dependent on the data format. In this case, however, the list integrity check value ICVrev, for checking the revocation list for tampering, is added to the partial integrity check values, ~~and~~. A all of these integrity check values are checked for tampering. If the total integrity check value equals the integrity check value ~~+~~ ICVt, stored in the header, it is determined that none of the ICVa and ICVb, the content block integrity check values, and the list integrity check value ICVrev have not been tampered with.

[0907] Further at step S907, the revocation list, which has been determined to be free from tampering, is compared with the recording and reproducing device ID (IDdev) stored in this recording and reproducing device 300.

[0908] If the list of invalid recording and reproducing device Ids, IDdev (read out from the content data) contains the identifier IDdev of this recording and reproducing device 300, this recording and reproducing device 300 is determined

to have illegally copied key data. The process then advances to step S909 to abort the subsequent procedure. For example, the process disables, for example, the execution of the content download process in Fig. 22.

[0909] At step S907, if the list of invalid recording and reproducing device IDs IDdev is determined not to contain the identifier IDdev of this recording and reproducing device 300, this recording and reproducing device 300 is determined to have valid key data. The process proceeds to step S908 to enable the subsequent procedure, for example, the program executing process or the content download process in Fig. 22 or other figures.

[0910] Fig. 88 shows a process executed to reproduce content data stored in the recording device 400, such as a memory card. As previously described, the recording device 400 (such as a memory card) and the recording and reproducing device 300 carry out the mutual authentication process described in Fig. 20 (step S921). Only if the mutual authentication is successful at step S922, does the process proceed to step S923 and the subsequent processing, ~~—~~. ~~Whereas~~ if the mutual authentication fails, an error occurs at step S930 to prevent the subsequent processing from being executed.

[0911] At step S923, the revocation list (see Fig. 86) is obtained from the header section of the content data. The processing at ~~the~~ subsequent steps S924 to 930 is similar to the corresponding processing in Fig. 87. That is, the list is verified with the list integrity check value (S924 and S925) and with the total integrity check value (S926 and S927), ~~and~~. ~~the~~ The list entry is compared with the recording and reproducing device ID IDdev (S928). Then, if the list of invalid recording and reproducing device IDs, IDdev, contains the identifier IDdev of this recording and reproducing device 300, this recording and reproducing device 300 is determined to have illegally copied key data. Then, ~~and~~ the process ~~then~~ advances to step S930 to abort the subsequent procedure. For example, the process disables, for example, the execution of the content reproduction process in Fig. 28. On the other hand,

if the list of invalid recording and reproducing device IDs, IDdev, is determined not to contain the identifier IDdev of this recording and reproducing device 300, this recording and reproducing device 300 is determined to have valid key data, and the process proceeds to step S929 to enable the subsequent procedure.

[0912] As described above, according to the present data processing apparatus, the data identifying invalid recording and reproducing devices 300, that is, the revocation list containing the identifiers IDdev of invalid recording and reproducing devices 300, is contained in the content (provided by the content provider or manager) as constituent data of the header section of the content data. Before using the content in the recording and reproducing device 300, the recording and reproducing device user collates the recording and reproducing device ID, IDdev (stored in the memory of this recording and reproducing device 300), with the ID in the list and prevents the subsequent processing if matching data are found. Consequently, the content can be prevented from being used by invalid recording and reproducing devices 300 that store copied key data in their memory.

(18) Method for Configuring and Manufacturing Secure Chip

[0913] As previously described, the internal memory 307 of the recording and reproducing device cryptography process section 302 or the internal memory 405 of the recording device 400 holds important information such as the cryptography keys and thus needs to be structured to reject external invalid reads. Thus, the recording and reproducing device cryptography process section 302, and the recording device cryptography process section 401, are configured as a tamper resistant memory. The tamper resistant memory is characterized to restrain external illegal reads in that it comprises, for example, a semiconductor chip that rejects external accesses and has a multilayer structure, an internal memory sandwiched between dummy layers of aluminum or the like or arranged in the lowest layer, and a narrow range of operating voltages and/or frequencies.

[0914] As understood from the above description, however, data such as the recording and reproducing device signature key (Kdev), which vary depending on the recording and reproducing device 300, must be written to the internal memory 307 of the recording and reproducing device cryptography process section 302. Additionally, data rewrites or reads must be difficult after individual information for each chip, (for example, identification information (ID) and encryption key information) has been written to a non-volatile storage area in the chip, for example, a flash memory or an FeRAM, for example, after shipment.

[0915] A conventional method for making data reads and rewrites difficult comprises, for example, making a data write command protocol secret, or separating signal lines on the chip for accepting the data write command from communication signal lines used after completion of the product, so that the data write command will not be effective unless the signal is directly transmitted to the chip ~~on a substrate~~.

[0916] Even with such a conventional method, however, those who have a technical knowledge of storage elements can output signals to a data write area of the chip if they have a facility and a technique for driving the circuit, and even if a data write command protocol is secret, there is always a possibility that the protocol may be analyzed.

[0917] Distribution of elements for storing cryptography process data, which allow secret data to be modified, may threaten the entire cryptography process system. In addition, to prevent data from being read out, it is possible to avoid implementing the data read command. In this case, however, even if a regular data write has been executed, it ~~is~~ may be impossible to determined whether or not the written data has been accurately written. This can ~~resulting in a~~ the possibility of supplying chips with inappropriate data written thereto.

[0918] In view of these conventional techniques, the present invention provides a secure chip configuration that enables data to be accurately written to a non-volatile memory, such as a flash memory or an FeRAM, while restraining data

from being read out therefrom, as well as a method for manufacturing such a secure chip.

[0919] Fig. 89 shows a security chip configuration applicable to, for example, the ~~above~~—above-described recording and reproducing device cryptography process section 302, or the cryptography process section 401 of the recording device 400. Fig. 89(A) shows a security chip configuration formed during a chip manufacturing process, that is, during a data write process, ~~and~~—Fig. 89(B) shows an example of the configuration of a product, such as the recording and reproducing device 300 or the recording device 400, which has a security chip mounted in the product and having data written thereto.

[0920] During the manufacturing process, a process section 8001 of the security chip has mode specifying signal lines 8003 and various command signal lines 8004 connected thereto ~~and~~. It writes or reads data to or from a storage section 8002. Storage section 8002 comprising—comprises a non-volatile memory, ~~and~~. Data is written or read depending on, for example, whether the chip is in a data write mode or a data read mode.

[0921] ~~On the other hand,~~—In the security chip mounted product in Fig. 89(B), the security chip is connected to an externally connected interface, peripheral equipment, and other elements via general purpose signal lines, ~~and~~. ~~whereas~~ ~~the~~ The mode signal lines 8003 are not connected. Specific processing for the mode signal lines 8003 includes connecting these lines 8003 to the—ground, increasing the voltage on these lines to Vcc, cutting them, sealing them with an insulator resin, etc. Such processing hinders the mode signal lines 8003 in the security chip from being accessed after shipment, thereby preventing data from being externally read out from the chip or written thereto.

[0922] Further, the security chip 8000 of this configuration hinders data from being written to the storage section 8002 while hindering written data from being read out therefrom, thereby preventing invalid data writes or reads even if a third person successfully accesses the mode signal

lines 8003. Fig. 90 shows a process flow of a data write to, or a data read from, the security chip of this configuration.

[0923] At step S951, the mode signal lines 8003 are set for a data write or read mode.

[0924] At step S952, authentication information is taken out from the chip. The security chip of this configuration stores information required for the authentication process, such as a password and key information for the authentication process for the cryptography technique, for example, by wires or the mask ROM configuration. At step S952, this authentication information is read out to execute the authentication process. If, for example, a regular data write jig and data read device are connected to the general purpose signal lines to execute the authentication process, the authentication will be successful (Yes at step S953). If, however, an invalid data write jig and data read device are connected to the general purpose signal lines to execute the authentication process, the authentication will fail (No at step S953), and the process is stopped. The authentication process can be executed, for example, in accordance with the mutual authentication process procedure previously described in Fig. 13. The process section 8001, shown in Fig. 89(A), has a configuration capable of such an authentication process. This can be implemented, for example, using a configuration similar to a command register integrated into the control section 403 of the cryptography process section 401 of the recording device 400 (shown in the previously described Fig. 29). For example, the process section of the chip in Fig. 89(A) has a configuration similar to the command register, integrated into the control section 403 of the cryptography process section 401 of the recording device 400 shown in Fig. 29. It carries out an appropriate process to enable the authentication process sequence to be executed, in response to an input of a predetermined command from an apparatus connected to the various command signal lines 8004.

[0925] ~~Only if the authentication process is successful,~~
The process section 8001 accepts the data write or read

command to execute the data write (step S955) or read (step S956) process only if the authentication process is successful.

[0926] As described above, the security chip of this configuration is configured to execute the authentication process on a data write or read, thereby preventing an unauthorized third person from reading or writing data to or from the storage section of the security chip.

[0927] ~~Next,~~ Fig. 91 shows an embodiment of a securer element configuration. In this example, the storage section 8200 of the security chip is separated into two areas. One of the areas is a Read Write (RW) area 8201, ~~to and from which~~ data can be written and read to and from. ~~while~~ The other section is a Write Only (WO) area 8202 ~~to which~~ data can only be written to.

[0928] In this configuration, cryptography key data, ID data, and other data which require high security are written to the Write Only ~~(WO)~~ area 8202, whereas integrity check data and other data which do not require so high security are written to the Read Write ~~(RW)~~ area 8201.

[0929] As a process for reading data out from the Read Write (RW) area 8201, the process section 8001 executes a data read process involving the authentication process described in the above described Fig. 90. The data write process, however, is executed following the flow in Fig. 92.

[0930] At step S961 in Fig. 92, the mode signal lines 8003 are set for the write mode, ~~and.~~ At step S962, an authentication process, similar to that described in the above Fig. 90, is executed. When the authentication process is successful, the process proceeds to step S963 to output to the process section 8001, a command for writing information such as key data which requires high security to the Write Only (WO) area 8202 via the command signal lines 8004, while writing check data or other data, which do not require a high a security, to the Read Write (RW) area 8201.

[0931] ~~At step S964,~~ On receiving the command, the process section 8001 executes a data write process at step S964. This is done on the Write Only (WO) area 8202 or the Read Write (RW) area 8201, depending on the command.

[0932] In addition, Fig. 93 shows ~~a flow of a~~ process for verifying data written to the Write Only (WO) area 8202.

[0933] At step S971 in Fig. 93, the process section 8001 causes the Write Only (WO) area 8202 to execute the cryptography process based on the written data. Like the above authentication process executing configuration, this execution configuration is implemented by a configuration for sequentially executing the cryptography process sequence stored in the command register. Additionally, the cryptography process algorithm executed in the process section 8001 is not particularly limited, ~~but~~. For example, the previously described DES algorithm can be carried out.

[0934] Then at step S972, a verification device (connected to the security chip) receives the result of the cryptography process from the process section 8001. Then at step S973, the result of the application of a cryptography process (similar to the algorithm executed by the process section 8001) on the regular write data written to the storage section at step S973 is compared with the result of encryption from the process section 8001.

[0935] If the compared results are identical, it is verified that the data written to the Write Only (WO) area 8202 ~~are~~ is correct.

[0936] With this configuration, if the authentication process should be deciphered to enable the read command to be executed, data can be read out only from the Read Write (RW) area 8201, while data written to the Write Only (WO) area 8202 cannot be read out; ~~thus~~. Thus this configuration provides much higher security. In addition, unlike chips that prohibit data reads, this chip includes the Read Write (RW) area 8201 to enable memory accesses to be validated.

[0937] This invention has been described with reference to the particular embodiments. Obviously, however, modifications or substitutions may be made to the present invention by those skilled in the art without deviating from the spirits thereof. That is, the present invention has been disclosed for illustrative purposes only and should not be interpreted in a restrictive manner. In addition, in the above described

embodiments, the recording and reproducing device, capable of recording and reproducing contents, ~~are~~ is described by way of example. However, the configuration of the present invention is applicable to apparatuses capable of ~~only either~~ recording or reproducing data, ~~and~~. ~~The present invention can be implemented in personal computers, game apparatuses, and other various data processing apparatuses in general. To determine the points of the present invention, the claims set forth at the beginning should be referenced.~~

[0938] Although the invention herein has been described with reference to particular embodiments, it is to be understood that these embodiments are merely illustrative of the principles and applications of the present invention. It is therefore to be understood that numerous modifications may be made to the illustrative embodiments and that other arrangements may be devised without departing from the spirit and scope of the present invention as defined by the appended claims.

Industrial Applicability

~~—The present invention can be utilized in apparatuses and systems which are capable of reproducing various contents such as sounds, images, games, and programs, which can be obtained via a storage medium, such as a DVD and a CD, or via various wired and radio communication means such as CATV, Internet, and satellite communication, in a recording and reproducing a user has, and storing the contents in a special recording device, such as a memory card, a hard disk, and a CD-R, and at the same time, of offering security in which the utilization that a contents provider wants is limited in the case of using the contents stored in the recording device, and a third party other than regular users is prevented from illegally using the provided contents.~~

1. (AMENDED) A data processing apparatus for processing content data provided by a recording or communication medium, ~~characterized in that said apparatus comprises~~comprising:

——a cryptography process section for executing a cryptography process on said content data; and

——a control section for executing control for said cryptography process section, and

——wherein said cryptography process section:

——~~is configured to generates~~ partial integrity check values as integrity check values for a partial data set, said partial data set containing ~~one or more~~ partial data obtained by a content data-constituting section ~~into a plurality of parts, and to~~

collates said~~the generated~~ integrity check values to verify said partial data, and

generates an intermediate integrity check value based on a partial integrity check value set ~~data string~~ containing at least one ~~or more~~ of said partial integrity check values, and

~~uses said the generated~~ intermediate integrity check value to verify ~~the entirety the of the plurality of said~~ partial data sets ~~corresponding to the plurality of partial integrity check values constituting said partial integrity check value set.~~

2. (AMENDED) The data processing apparatus according to Claim 1, ~~characterized in that~~wherein:

said partial integrity check values ~~is are~~ generated by means of a said cryptography process with a partial-check-value-generating key applied thereto, using said partial data ~~to be checked, as a message,~~

said intermediate integrity check value is generated by means of a said cryptography process with an general-check-value-generating key applied thereto, using a said partial

integrity check value set ~~data string to be checked~~, as a said message, ~~;~~ and

said cryptography process section is configured to store said ~~partial-integrity-check-value-generating value-key~~ and said ~~general-integrity-check-value-generating~~ key.

3. (AMENDED) The data processing apparatus according to Claim 1, ~~characterized in that:wherein~~ said cryptography process has plural types of ~~partial-check-value-generating keys~~ corresponding to ~~generated~~ said partial integrity check values.

4. (AMENDED) The data processing apparatus according to Claim 2, ~~characterized in thatwherein~~:

said cryptography process is a DES cryptography process, and

said cryptography process section is configured to execute saidthe DES cryptography process.

5. (AMENDED) The data processing apparatus according to Claim 2, ~~characterized in thatwherein~~:

said partial integrity check values ~~is~~ are a message authentication codes ~~(MAC)~~ generated in a DES-CBC mode using said partial data to be checked, as a said message, ~~;~~

said intermediate integrity check value is a ~~one of~~ said message authentication codes ~~(MAC)~~ generated in a said DES-CBC mode using a said partial integrity check value set ~~data string to be checked~~, as a said message, and

said cryptography process section is configured to execute saidthe cryptography process in saidthe DES-CBS mode.

6. (AMENDED) The data processing apparatus according to Claim 5, ~~characterized in that:wherein~~ Triple DES is applied in part of a message string to be processed in saidthe DES-CBC

~~mode-based cryptography process configuration of said cryptography process section, Triple DES is applied only in part of a message string to be processed.~~

7. (AMENDED) The data processing apparatus according to Claim 1, ~~characterized in that~~further comprising:

~~said data processing apparatus has a signature key,~~
wherein: and

said cryptography process section+ is configured to apply a value generated from said intermediate integrity check value by means of said signature key ~~applied cryptography process~~ as a collation value for data verification.

8. (AMENDED) The data processing apparatus according to Claim 7, ~~characterized in that~~wherein:

said signature key~~data processing apparatus has~~
includes a plurality of different signature keys ~~as signature keys,~~; and

said cryptography process section+ is configured to apply one of said plurality of different signature keys, which is selected depending on a localization of said content data, to said~~the~~ cryptography process for said intermediate integrity check value to obtain said~~the~~ collation value for data verification.

9. (AMENDED) The data processing apparatus according to Claim 8, ~~characterized in that: said data processing apparatus has~~further comprising:

~~—a common signature key common to all entities of a system for executing a data verifying process;~~ and

an apparatus-specific signature key specific to each apparatus that executes a said data verifying process.

10. (AMENDED) The data processing apparatus according to Claim 1, ~~characterized in that~~wherein:

said partial integrity check values contains at least one ~~or more~~ header section integrity check values ~~generated for intra-header-section data partly constituting data~~ and at least one ~~or more~~ content integrity check values, said at least one header section integrity check value being generated for intra-header-section data partly constituting data and said at least one content integrity check value being generated for content block data partly constituting ~~said the data,~~; and

said cryptography process is configured to generate at least one ~~or more~~ header section integrity check values for ~~a~~ said partial data set in said intra-header-section data to execute a collation process, generate at least one ~~or more~~ content integrity check values for ~~a~~ said partial data set in said intra-content-section data to execute ~~a~~ said collation process, and further generate a general integrity check value based on all of said header section integrity check values and said content integrity check values ~~generated,~~ to execute a said collation process in order to verify said the data.

11. (AMENDED) The data processing apparatus according to Claim 1, ~~characterized in that~~wherein:

said partial integrity check values contains at least one ~~or more~~ header section integrity check values generated for intra-header-section data partly constituting data~~,~~; and

said cryptography process is configured to generate at least one ~~or more~~ header section integrity check values for ~~a~~ said partial data set in said intra-header-section data to execute a collation process and further generate a general integrity check value based on said at least one ~~or more~~ header section integrity check values ~~generated~~ and on content

block data constituting part of said data, to execute a said collation process in order to verify said ~~the~~ data.

12. (AMENDED) The data processing apparatus according to Claim 1, ~~characterized by further comprising~~ a recording device for storing data validated by said cryptography process section.

13. (AMENDED) The data processing apparatus according to Claim 12, ~~characterized in that~~ wherein:

~~said control section is configured so that if in the process executed by said cryptography process section to collate the partial integrity check value, the collation is not established, and~~

~~—said control section suspends the process for storing of~~ said data in said recording device if a process of collating said partial integrity check values is not established in said cryptography process executed by said cryptography process section.

14. (AMENDED) The data processing apparatus according to Claim 1, ~~characterized by further comprising~~ a reproduction process section for reproducing data validated by said cryptography process section.

15. (AMENDED) The data processing apparatus according to Claim 14, ~~characterized in that~~ wherein:

~~—if in the process executed by said cryptography process section to collate the partial integrity check value, the collation is not established, and~~

~~said control section suspends the reproducing of~~ said data reproduction process in said reproduction process section if a process of collating said partial integrity check

values is not established in said cryptography process executed by said cryptography process section.

16. (AMENDED) The data processing apparatus according to Claim 14, further comprising:

control means for collating only ~~the~~ header section integrity check values in said~~the~~ data during said~~the~~ cryptography process executed by said cryptography process section to collate said~~the~~ partial integrity check values; and

transmitting to said reproduction process section said data for which collation of said~~the~~ header section integrity check values has been established, ~~to said reproduction process section for reproduction.~~

17. (AMENDED) A data processing apparatus for processing content data provided by a recording or communication medium, ~~characterized in that said apparatus comprises~~comprising:

a cryptography process section for executing a cryptography process on said content data; and

a control section for executing control for said cryptography process section, and wherein

if data to be verified is encrypted data said cryptography process section: ~~is configured to generate,~~ if data to be verified are encrypted, integrity check values for said~~the~~ data ~~to be verified by means of a signature data-~~ applied cryptography process ~~from~~ data on arithmetic operation results obtained by executing an arithmetic operation process on decrypted data obtained by executing a decryption process on said~~the~~ encrypted data.

18. (AMENDED) The data processing apparatus according to Claim 17, ~~characterized in that, wherein~~ said arithmetic operation process comprises performing an exclusive-OR operation on said decrypted data every at predetermined bytes,

~~said~~the decrypted data being obtained by decrypting said encrypted data.

19. (AMENDED) A data processing method for processing content data provided by a recording or communication medium, ~~characterized in that~~said method comprising:

~~generates~~generating partial integrity check values as integrity check values for a partial data set, said partial data set containing ~~one or more~~partial data obtained by a content data ~~constituting section into a plurality of parts,~~;

~~and collates~~collating the ~~generated~~said integrity check values to verify said partial data,~~and;~~;

~~generates~~generating an intermediate integrity check value based on a partial integrity check value set ~~data string~~ containing at least one ~~or more~~ of said partial integrity check values,~~;~~; and

~~verifying~~said the ~~entirety of the plurality of~~ partial data sets corresponding to the ~~plurality of~~ said partial integrity check values using said intermediate integrity check value. ~~constituting said partial integrity check value set.~~

20. (AMENDED) The data processing method according to Claim 19, ~~characterized in that~~wherein:

~~said~~ partial integrity check values ~~is~~are generated by means of a cryptography process with a partial-check-value-generating key applied thereto, using said partial data as a message,~~;~~; and

~~said~~ intermediate integrity check value is generated by means of a ~~said~~ cryptography process with an general-check-value-generating key applied thereto, using a ~~said~~ partial integrity check value set ~~data string to be checked,~~ as a said message.

21. (AMENDED) The data processing method according to Claim 20, ~~characterized in that: wherein~~ said partial integrity check values ~~is~~ are generated by applying different types of said partial-check-value-generating keys corresponding to ~~generated~~ partial integrity check values.

22. (AMENDED) The data processing method according to Claim 20, ~~characterized in that: wherein~~ said cryptography process is a DES cryptography process.

23. (AMENDED) The data processing method according to Claim 19, ~~characterized in that: wherein~~:

said partial integrity check values include ~~is~~ a message authentication code ~~(MAC)~~ generated in a DES-CBC mode using said partial data ~~to be checked,~~ as a message, ~~;~~ and

said intermediate integrity check value is a ~~said~~ message authentication code ~~(MAC)~~ generated in a ~~said~~ DES-CBC mode using a ~~said~~ partial integrity check value set data ~~string to be checked,~~ as said message.

24. (AMENDED) The data processing method according to Claim 19, ~~characterized in that: wherein~~ a value generated from said intermediate integrity check value by means of a signature key-applied cryptography process is applied as a collation value for data verification.

25. (AMENDED) The data processing method according to Claim 24, ~~characterized in that: wherein~~ different signature keys are applied to said the cryptography process for said intermediate integrity check value depending on a localization of ~~said~~ content data, said different signature keys being applied to obtain said the collation value for data verification.

26. (AMENDED) The data processing method according to Claim 25, ~~characterized in that~~further comprising:

selecting and using one of
a common signature key common to all entities of a system for executing a data verifying process; ~~or~~and
-an apparatus-specific signature key specific to each apparatus that executes a said data verifying process,
said selecting step being based is selected and used
~~as said signature key depending on the localization of~~ said
the content data.

27. (AMENDED) The data processing method according to Claim 19, ~~wherein characterized in that~~

said partial integrity check values contains at least one—~~or more~~ header section integrity check values generated for intra-header section data partly constituting data and at least one—~~or more~~ content integrity check values generated for intra-content section data partly constituting ~~said~~the data; ~~and~~ said method further comprising:

~~—a data verifying process—~~

~~—generates~~ generating at least one—~~or more~~ header section integrity check values for saida partial data set in said intra-header-section data to execute a collation process;

~~generates~~ generating at least one—~~or more~~ content integrity check values for saida partial data set in said intra-content-section data to execute a ~~a—~~said collation process; and

~~—and~~

generating ~~further generates~~ a general integrity check value based on all of said header section integrity check values and said content integrity check values generated, said general integrity check value being operable to execute a—said collation process in order to verify saidthe data.

28. (AMENDED) The data processing method according to Claim 19, ~~wherein~~characterized in that:

said partial integrity check values contains at least one or more header section integrity check values generated for intra-header section data partly constituting data, said method further comprising: and

~~generates~~

generating at least one or more header section integrity check values for asaid partial data set in said intra-header-section data to execute a collation process; and

~~further generates~~ generating a general integrity check value based on said at least one or more header section integrity check values ~~generated~~ and on content block data constituting part of said data, said general integrity check value being operable to execute a said collation process in order to verify said the data.

29. (AMENDED) The data processing method according to Claim 19, ~~characterized by further comprising: a process for storing, after data verification,~~ storing validated data after verifying said partial data set.

30. (AMENDED) The data processing method according to Claim 29, ~~characterized in that: further comprising suspending said storing of said validated data if in the process for collating of said partial integrity check values, the collation is not established, control is executed such as to suspend the process for storing data in said recording device.~~

31. (AMENDED) The data processing method according to Claim 19, ~~characterized by further comprising: a data reproduction process for reproducing data after~~ verifying said the partial data verification set.

32. (AMENDED) The data processing method according to Claim 31, ~~characterized in that~~ further comprising:

suspending said reproducing of said data if collating of said partial integrity check values is not established.

~~if in the process for collating said partial integrity check value, the collation is not established, and
control is executed such as to suspend the reproduction process executed in said reproduction process section.~~

33. (AMENDED) The data processing method according to Claim 31, ~~characterized in that said method~~ wherein:

said collating of said the partial integrity check values only collates header section integrity check values and transmits said data for which collation of said the header section integrity check values has been established, to said a reproduction process section for reproduction.

34. (AMENDED) The ~~A~~ data processing method for processing content data provided by a recording or communication medium, the method ~~being characterized in that said method~~ comprising:

decrypting encrypted data to be verified to obtain decrypted data;

~~if data to be verified are encrypted, executes~~
executing an arithmetic operation process on said decrypted data to obtain results obtained by decrypting the encrypted data,; and

~~executes~~ executing a signature key-applied cryptography process ~~on data on said arithmetic operation results obtained by said arithmetic operation,~~ to generate integrity check values for said data to be verified.

35. (AMENDED) The data processing method according to Claim 34, ~~characterized in that:wherein~~ said arithmetic operation process comprises performing an exclusive-OR operation on said decrypted data ~~every at predetermined bytes, the decrypted data being obtained by decrypting said encrypted data.~~

36. (AMENDED) A data verifying value imparting method for a data verifying process, ~~characterized in that~~ said method comprising:

~~imparts~~ imparting partial integrity check values as integrity check values for a partial data set, said partial data set containing ~~one or more~~ partial data obtained by a content data—~~constituting section into a plurality of parts,~~
; and

~~imparts~~ imparting ~~to data to verified,~~ an intermediate integrity check value to data to be verified, said intermediate integrity check value being used to verify a partial integrity check value set ~~data string~~ containing at least one ~~or more~~ of said partial integrity check values.

37. (AMENDED) The data verifying value imparting method according to Claim 36, ~~characterized in that:wherein~~:

said partial integrity check values ~~is~~ are generated by means of a cryptography process with a partial-check-value-generating key applied thereto, using said partial data ~~to be checked,~~ as a message; i and

said intermediate integrity check value is generated by means of a said cryptography process with an a general-check-value-generating key applied thereto, using a said partial integrity check value set ~~data string to be checked,~~ as a said message.

38. (AMENDED) The data verifying value imparting method according to Claim 37, ~~characterized in that:wherein~~ said

partial integrity check values ~~is~~ are generated by applying different types of said partial-check-value-generating keys corresponding to ~~generated~~ said partial integrity check values.

39. (AMENDED) The data verifying value imparting method according to Claim 37, ~~characterized in that:~~ wherein said cryptography process is a DES cryptography process.

40. (AMENDED) The data verifying value imparting method according to Claim 36, ~~characterized in that~~ wherein:

said partial integrity check values ~~is~~ include a message authentication code (MAC) ~~generated in a DES-CBC mode using~~ said partial data ~~to be checked, as a message,~~; and

said intermediate integrity check value is a ~~said~~ message authentication code (MAC) ~~generated in a~~ said DES-CBC mode using a ~~said~~ partial integrity check value set data ~~string to be checked, as a~~ said message.

41. (AMENDED) The data verifying value imparting method according to Claim 36, ~~characterized in that:~~ wherein a value generated from said intermediate integrity check value by means of a signature key-applied cryptography process is applied as a collation value for data verification.

42. (AMENDED) The data verifying value imparting method according to Claim 41, ~~characterized in that:~~ wherein different signature keys are applied to ~~the~~ said cryptography process for said intermediate integrity check value to obtain said collation value, said different signature keys being applied depending on a localization of ~~said~~ content data, ~~to obtain the collation value for data verification.~~

43. (AMENDED) The data verifying value imparting method according to claim 42, ~~characterized in that~~further comprising:

selecting either a common signature key common to all entities of a system for executing a data verifying process or an apparatus-specific signature key specific to each apparatus that executes a data verifying process is selected and used as one of said different signature keys depending upon the localization of the said content data, said common signature key being common to all entities of a system for executing said data verifying process, and said apparatus-specific signature key being specific to each apparatus that executes said data verifying process.

44. (AMENDED) The data verifying value imparting method according to Claim 36, ~~characterized in that~~wherein:

said partial integrity check values contains at least one or more header section integrity check values for in intra-header section data partly constituting data and at least one or more content integrity check values generated for intra-content-section data partly constituting said the data, and

said method is set so that further comprising:

generating a general integrity check value is generated to verify said data for all said at least one header section integrity check values and said at least one content integrity check values, to verify the data.

45. (AMENDED) The data verifying value imparting method according to Claim 36, ~~characterized in that~~wherein:

said partial integrity check values contains at least one or more header section integrity check values for intra-header-section data partly constituting data, and

said method further comprising:

generating a general integrity check value is generated to verify said data, said general integrity check value being generated for said at least one or more header section integrity check values and content block data partly constituting said data, to verify the data.

46. (AMENDED) A recording program providing medium for providing recorded with a computer program for causing a data verifying process to be executed executing a data verifying process having certain actions, said actions comprising on a computer system to verify that data are valid, the program providing medium being characterized in that said computer program comprises steps of:

executing a collation process using partial integrity check values generated as integrity check values for a partial data set containing one or more partial data obtained by dividing data a plurality of parts,; and

using an intermediate integrity check value based on a partial integrity check value set obtained by combining a plurality of said partial integrity check values together, to verify the entirety of a plurality of said partial data sets, said intermediate integrity check value being based on a partial integrity check value set obtained by combining at least some of said partial integrity check values together, and said partial data set corresponding to said the plurality of partial integrity check values constituting said partial integrity check value set.

47. (AMENDED) A data processing apparatus, comprising:

an encryption processing section that executes encryption processing including ~~at least one of data encryption, data decryption, data verification, authentication processing and signature processing; and~~

a storage section that stores master keys to generate keys used for said encryption processing,

~~characterized in that~~wherein said encryption processing section is configured to generate individual keys ~~for executing necessary to execute~~ said encryption processing based on one of said master keys, an encryption processing target apparatus, ~~and~~ data identification data.

48. (AMENDED) The data processing apparatus according to Claim 47, ~~characterized in that~~ wherein:

~~said data processing apparatus is a data processing apparatus that~~ encryption processing section performs said encryption processing on transfer data via a storage medium or a communication medium;

said storage section stores a distribution key generation master key MKdis for generating a distribution key Kdis, said distribution key Kdis being used for said encryption processing of said transfer data; and

said encryption processing section executes said encryption processing based on said ~~the~~ distribution key generation master key MKdis ~~stored in said storage section and~~ a data identifier, said data identifier which is ~~including~~ identification data of said transfer data ~~and generates said transfer data distribution key Kdis.~~

49. (AMENDED) The data processing apparatus according to Claim 47, wherein; ~~characterized in that~~

~~—~~ ~~said data processing apparatus is a data processing apparatus that~~ performs authentication processing of an externally connected apparatus ~~to/from~~ which data is transferred to or from;

said storage section stores an authentication key generation master key MKake for generating an authentication key Kake of said externally connected apparatus, ~~;~~ and

said encryption processing section executes said encryption processing based on said the authentication key generation master key MKake ~~stored in said storage section and~~ an externally connected apparatus identifier, said externally connected apparatus identifier including which is identification data of said externally connected apparatus ~~and generates the authentication key Kake of said externally connected apparatus.~~

50. (AMENDED) The data processing apparatus according to Claim 47, wherein:

~~characterized in that~~ said encryption data processing ~~section~~ apparatus is a data processing apparatus that performs said signature processing on data;

said storage section stores a signature key generation master key MKdev for generating a data processing apparatus signature key Kdev of said data processing apparatus, ~~;~~ and

said encryption processing section executes said ~~encryption~~ signature processing based on said the signature key generation master key MKdev ~~stored in said storage section and~~ a data processing apparatus identifier, said data processing apparatus identifier including which is identification data of said data processing apparatus ~~and generates the data processing apparatus signature key Kdev of said data processing apparatus.~~

51. (AMENDED) The data processing apparatus according to Claim 47, wherein said encryption processing section performs ~~characterized in that~~ individual key generation processing ~~that to~~ generates an said individual keys necessary to execute for executing said encryption processing based on said master keys and identification data ~~of the apparatus or data subject to encryption processing is,~~ said encryption processing that

~~using said at least part of~~ identification data ~~of the apparatus or data subject to encryption processing as a message and applies~~ applying said master keys as the encryption keys.

52. (AMENDED) The data processing apparatus according to Claim 51, ~~characterized in that~~wherein said encryption processing ~~is encryption processing using~~uses a DES algorithm.

53. (AMENDED) A data processing system ~~configured by a plurality of data processing apparatuses, characterized in that~~comprising:

a plurality of data processing apparatuses;

~~each of said plurality of data processing apparatuses having a common master key to generate a key used for encryption processing~~ including ~~at least one of data encryption, data decryption, data verification, authentication processing and signature processing,~~ each of said plurality of data processing apparatuses having said common master key; and

~~each of said plurality of data processing apparatuses generating a common individual key for executing necessary to execute~~ said encryption processing based on said master key and identification data, each of said plurality of data processing apparatuses generating said common individual key of the apparatus or data subject to encryption processing.

54. (AMENDED) The data processing system according to Claim 53, ~~characterized in that~~ further comprising:

~~said plurality of data processing apparatuses is configured by a contents data providing apparatus~~ operable to configure said plurality of data processing apparatuses and to supply that supplies contents data; and

a contents data utilization apparatus that utilizes ~~said~~the contents data,

both ~~said~~the contents data providing apparatus and said contents data utilization apparatus ~~have~~having a distribution key generation master key to generate a contents data distribution key, said contents data distribution key being used for said encryption processing of circulation contents data between said contents data providing apparatus and said contents data utilization apparatus,

~~said contents data providing apparatus generates generating a~~said contents data distribution key based on said distribution key generation master key and a contents identifier, said contents identifier being which is an identifier of supplied said contents data and executes encryption processing on said contents data, and

~~said contents data utilization apparatus generates generating a~~said contents data distribution key based on said distribution key generation master key and said contents identifier, which is an identifier of supplied contents data and executes decryption processing on said contents data.

55. (AMENDED) The data processing system according to Claim 54, ~~characterized in that wherein:~~

~~said contents data providing apparatus has a plurality of different distribution key generation master keys to generate a plurality of different contents data distribution keys,~~ generates a plurality of different contents data distribution keys based on ~~a~~said plurality of different distribution key generation master keys and said contents identifier, executes said encryption processing using said plurality of different contents data distribution keys, ~~generated and generates encryption contents data of~~having a plurality of types, and

said contents data utilization apparatus has at least one of said distribution key generation master key of the plurality of different distribution key generation master keys, ~~owned by said contents data providing apparatus~~ and makes decodable only said encryption contents data formed by a distribution key generated using the same one of said different distribution key generation master keys that is the same as the a distribution key generation master key owned by the ownan apparatus.

56. (AMENDED) The data processing system according to Claim 53, ~~characterized in that~~ further including:

~~each of said plurality of data processing apparatuses stores a same a contents key generation master key to generate a contents key used for said encryption processing of contents data, said contents key generation master key being stored in each of said plurality of data processing apparatuses;~~

~~data processing apparatus A, which is a first one of said plurality of data processing apparatuses, stores storing said contents data in a storage medium, said contents data being encrypted by a said contents key key generated based on said contents key generation master key and the an apparatus identifier of said first one of said plurality of data processing apparatuses data processing apparatus A in a storage medium;~~ and

~~different a second one of said plurality of data processing apparatuses B generating a said contents key based on said same contents key generation master key and said the apparatus identifier of said first one of said plurality of data processing apparatuses A, and executing decryption processing on the encrypted said contents data stored by said data processing apparatus A in said storage medium based on said contents key generated.~~

57. (AMENDED) The data processing system according to Claim 53, ~~characterized in that~~further including:

~~said plurality of data processing apparatuses are configured by a host device~~ having an authentication key generation master key; and

a slave device subject to authentication processing by said host device, said slave device having said authentication key generation master key and a slave device identifier, said authentication key generation master key being used for authentication processing between said host device and said slave device, wherein:

~~both said host device and said slave device have an authentication key generation master used for authentication processing between the host device and slave device,~~

said slave device generates an authentication key based on said authentication key generation master key and said slave device identifier, said slave device identifier being which is thean identifier of said slave device and being stored in a memory in of thesaid slave device, and

said host device generates an said authentication key based on said authentication key generation master key and saidthe slave device identifier, ~~which is the identifier of said slave device and executes authentication processing, and~~

said plurality of data processing apparatuses are configured by said host device and said slave device.

58. (AMENDED) A data processing method that executes encryption processing includingef at least one of data encryption, data decryption, data verification, authentication processing and signature processing, said data processing method comprising:

~~a key generating step of generating individual keys necessary to execute encryption processing based on master keys to generate the key used for said encryption processing and identification data of an externally connected~~the apparatus or data subject to said encryption processing; and
~~an encryption processing step of executing said encryption processing based on the key generated in said key generating stepsaid individual keys.~~

59. (AMENDED) The data processing method according to Claim 58, ~~characterized in that~~wherein said encryption processing data processing executed by said data processing method is executed encryption processing on transfer data via a storage medium or a communication medium;

~~said key said step of generating said individual keys includes step is a distribution key generating step of executing encryption processing based on a distribution key generation master key MKdis for generating a distribution key Kdis used for encryption processing of transfer data and a data identifier, which is identification data of said transfer data, and generating a distribution key Kdis of said transfer data, said distribution key Kdis being used for encryption processing of said transfer data, and said data identifier including said identification data of said transfer data; and~~

~~said encryption processing step is a step of executing said encryption processing step includes executing encryption processing on said transfer data based on saidthe distribution key Kdis generated in said distribution key generating step.~~

60. (AMENDED) The data processing method according to Claim 58, ~~characterized in that~~

~~said encryptiondata processing executed by said data processing method is authentication processing of thean~~

externally connected apparatus to/ and from which said data is transferred₇;

~~said key~~ said step of generating step ~~is an authentication key generating step of~~ said individual keys includes executing said encryption processing and generating an authentication key Kake, said encryption processing being based on an authentication key generation master key MKake for generating an authentication key Kake of said externally connected apparatus and an externally connected apparatus identifier, said externally connected apparatus identifier including which is said identification data of said externally connected apparatus₇; ~~and generating said authentication key Kake of said externally connected apparatus, and~~

said step of executing said encryption processing step ~~is~~ includes a step of executing said authentication processing of said ~~the~~ externally connected apparatus based on said ~~the~~ authentication key Kake generated in said authentication key generating step.

61. (AMENDED) The data processing method according to Claim 58, ~~characterized in that~~ wherein:

~~data~~ said encryption processing executed by said data processing apparatus is said signature processing on said data₇;

~~said key~~ said step of generating step ~~said individual keys is~~ includes a signature key generating step of executing said signature ~~encryption~~ processing based on a signature key generation master key Mkdev and a data processing apparatus identifier, and generating a data processing apparatus signature key Kdev of a data processing apparatus, said signature key generation master key Mkdev being operable to generate ~~for generating a~~ said data processing apparatus signature key Kdev of said data processing apparatus and a data processing apparatus

identifier, and said data processing apparatus identifier
~~being which is identification data of said data processing~~
~~apparatus and generating the data processing apparatus~~
~~signature key Kdev of said data processing apparatus, ; and~~

~~said encryption processing step is a step of~~includes
executing said signature processing on said data based on
~~the said signature key Kdev generated in said signature key~~
~~generating step.~~

62. (AMENDED) The data processing method according to
Claim 58, ~~characterized in that~~wherein ~~said key step of~~
~~generating step~~said individual keys isincludes executing said
encryption processing ~~that uses~~ using at least part of said
data identification of ~~the~~ said externally connected apparatus
or said data subject to said encryption processing as a
message, and ~~applies~~applying said master keys as the
encryption keys.

63. (AMENDED) The data processing method according to
Claim 62, ~~characterized in that~~wherein ~~said encryption~~
~~processing is encryption processing using~~uses a DES algorithm.

64. (AMENDED) A data processing method ~~in a data processing~~
~~system,~~ comprising:

a contents data providing apparatus that supplies
contents data, said contents data providing apparatus being
operable to generate a contents data distribution key based on
a distribution key generation master key and a contents
identifier, said contents identifier being an identifier of
said contents data and said contents data providing apparatus
being operable to execute encryption processing on said
contents data; and

a contents data utilization apparatus that utilizes
~~the~~said contents data, ~~characterized in that~~

~~—said contents data providing apparatus generates a contents data distribution key based on a distribution key generation master key for generating a contents data distribution key used for encryption processing on contents data and a contents identifier, which is the identifier of the provided contents data and executes encryption processing on said contents data, and~~

~~—said contents data utilization apparatus being operable to generates a said contents data distribution key based on said distribution key generation master key and a said contents identifier, which is the identifier of the provided contents data and executes decryption processing on said contents data.~~

65. (AMENDED) The data processing ~~method~~ system according to Claim 64, ~~characterized in that~~ wherein:

~~—said contents data providing apparatus has a plurality of different distribution key generation master keys to generate a plurality of different contents data distribution keys, generates a plurality of different contents data distribution keys based on said a plurality of different distribution key generation master keys and said contents identifier, executes said encryption processing using said plurality of different contents data distribution keys, generated and generates encryption contents data having of a plurality of types, and~~

~~said contents data utilization apparatus has at least one of said distribution key generation master key of the plurality of different distribution key generation master keys, owned by said contents data providing apparatus and decrypts only said encryption contents data formed by a distribution key generated using the same one of said different distribution key generation master keys that is the~~

~~same~~ as ~~the~~ a distribution key generation master key owned by ~~the own~~ an apparatus.

66. (AMENDED) A data processing method in a data processing system configured by a plurality of data processing apparatuses, said method comprising:

~~a step of storing, by data processing apparatus A, which is one of said plurality of data processing apparatuses, in a storage medium contents data~~ in a storage medium, said contents data being encrypted using a contents key-generated based on a contents key generation master key and being stored by a data processing apparatus A, and said contents key being generated based on a contents data generation master key to generate a contents key used for encryption processing of contents data and the an apparatus identifier of said data processing apparatus A;

~~a step of generating~~ said ~~the same~~ contents key as ~~said contents key by~~ with a different data processing apparatus B based on ~~the same~~ said contents key generation master key ~~as that of said data processing apparatus A and~~ said ~~the~~ apparatus identifier ~~of said data processing apparatus A; and~~

~~a step of decrypting~~ said ~~the~~ contents data stored in said storage medium using said ~~the~~ contents key generated by said data processing apparatus B.

67. (AMENDED) A data processing method in a data processing system including a host device and a slave device subject to authentication processing by said host device, said data processing method comprising:

~~— a host device; and~~
~~— a slave device subject to authentication processing by said host device, characterized in that~~

~~— said slave device generates~~ generating an authentication key in said slave device based on an

~~authentication key generation master key to generate an authentication key used for authentication processing between the host device and slave device and a slave device identifier, said authentication key being used for said authentication processing between said host device and said slave device, which said slave device identifier being~~ is the an identifier of said slave device;

~~and stores storing said~~ the authentication key generated in a memory in said slave device; and

~~said host device generates generating an said authentication key in said host device based on said authentication key generation master key and said slave device identifier, which is the identifier of said slave device; and executes executing said authentication processing.~~

68. (AMENDED) A ~~recording program providing medium recorded with that supplies a computer program for to execute executing encryption processing having certain actions to perform of at least one of data encryption, data decryption, data verification, authentication processing and signature processing on a computer system, said computer program actions comprising:~~

~~a key generating step of generating individual keys necessary to execute said encryption processing based on said master keys to generate the keys used for said encryption processing and identification data of the apparatus or data subject to encryption processing; and~~

~~an encryption processing step of executing said encryption processing based on said the individual keys generated in said key generating step.~~

69. (AMENDED) A data processing apparatus that processes contents data supplied from a storage medium or communication medium, comprising:

a storage section that stores data processing apparatus identifiers;

a list verification section that extracts an illegal device list included in ~~said~~the contents data and executes collation between entries ~~in~~ef said illegal device list and said data processing apparatus identifiers stored in said storage section; and

a control section that ~~terminates~~stops—executing processing of at least—either one of reproduction of said contents data or processing of storage in a recording device when ~~a~~the result of ~~said~~the collation ~~processing in said collation processing section~~ shows that said illegal device list includes information that matches said data processing apparatus identifiers.

70. (AMENDED) The data processing apparatus according to Claim 69, ~~characterized in that~~wherein:

—said list verification section comprises an encryption processing section that executes encryption processing on said contents data; and

said encryption processing section verifies the presence or absence of tampering in said illegal device list based on check values of ~~said~~the illegal device list included in said contents device and executes said collation ~~processing~~ only when said verification proves no tampering.

71. (AMENDED) The data processing apparatus according to Claim 70, further comprising an illegal device list check value generation key, ~~characterized in that~~wherein said encryption processing section executes said encryption processing by applying said illegal device list check value generation key to illegal device list configuration data to be verified, generates illegal device list check values, executes collation between said illegal device list check values and

the illegal device list check values included in said contents data and thereby verifies the presence or absence of tampering in said illegal device list.

72. (AMENDED) The data processing apparatus according to Claim 69, ~~characterized in that~~wherein:

said list verification section comprises an encryption processing section that executes encryption processing on said contents data; and

said encryption processing section executes decryption processing of ~~the~~an encrypted illegal device list included in said contents data to produce a decrypted illegal device list, and executes said collation ~~processing on said the decrypted illegal device list resulting from said decryption processing.~~

73. (AMENDED) The data processing apparatus according to Claim 69, ~~characterized in that~~wherein:

said list verification section comprises an encryption processing section that executes mutual authentication processing with a recording device ~~to/from~~ which and from which said contents data is transferred; and

said list verification section extracts ~~said the~~ illegal device list included in said contents data and executes said collation with said data processing apparatus identifiers stored in said storage section on condition that authentication with said recording device has been established through said mutual authentication processing executed by said encryption processing section.

74. (AMENDED) A data processing method that processes contents data supplied from a storage medium or communication medium, comprising:

~~a list extracting step of extracting~~ an illegal device list included in said~~the~~ contents data;

~~a collation processing step of executing~~ collation between entries included in said~~the~~ illegal device list ~~extracted in said list extracting step and said data processing apparatus identifiers stored in a storage section in the~~a data processing apparatus; and

~~a step of stopping~~ execution of processing of at least ~~either one of reproduction of said contents data or processing of storage in a recording device when the~~a result of said~~the~~ collation ~~processing in said collation processing~~ step shows that said illegal device list includes information that matches said data processing apparatus identifiers.

75. (AMENDED) The data processing method according to Claim 74, further comprising ~~a verification step of~~

verifying the presence or absence of tampering in said illegal device list based on check values of said~~the~~ illegal device list included in said contents data,; and

~~characterized in that said executing said collation processing step executes collation processing only when said verification step~~verifying step proves no tampering.

76. (AMENDED) The data processing method according to Claim 75, wherein~~characterized in that~~ said verification ~~step comprising~~verifying step includes:

~~a step of~~ executing encryption processing by applying an illegal device list check value generation key to illegal device list configuration data to be verified and generating illegal device list check values; and

~~a step of~~ executing collation between said~~the~~ illegal device list check values ~~generated and~~ said~~the~~ illegal device list check values included in said contents data and

thereby verifying the presence or absence of tampering in said illegal device list.

77. (AMENDED) The data processing method according to Claim 74, further comprising ~~a decrypting step of executing~~ decrypting processing on ~~the~~ an encrypted illegal device list included in said contents data to produce a decrypted illegal device list; and

~~characterized in that said executing collation processing step executes~~ said collation processing on said the decrypted illegal device list ~~resulting from said decrypting step.~~

78. (AMENDED) The data processing method according to Claim 74, further comprising ~~a mutual authentication processing step of~~

executing mutual authentication processing with a recording device ~~to/from~~ which and from which said contents data is transferred; ~~characterized in that, wherein~~

~~said collation processing step executes~~ collation processing is performed on condition that authentication with said recording device has been established through ~~mutual authentication processing executed in~~ said mutual authentication processing step.

79. (AMENDED) A contents data generation method, comprising:

~~that generating~~ contents data ~~supplied from a storage medium or communication medium to a plurality of recorders/~~ or a plurality of reproducers, said contents data being supplied from a storage medium or a communication medium; and

storing ~~characterized in that~~ an illegal device list as the header information of the contents data, said illegal device list having ~~whose component data comprises~~ comprising

identifiers of said plurality of recorders/ or said plurality of reproducers,

whereby said illegal device list ~~which will be excluded from the use of said contents data is stored as the header information of the contents data.~~

80. (AMENDED) The contents data generation method according to Claim 79, ~~characterized in that~~wherein illegal device list check values for a tampering check on said illegal device list are stored as ~~the~~said header information of ~~said~~the contents data.

81. (AMENDED) The contents data generation method according to Claim 79, ~~characterized in that~~wherein said illegal device list is encrypted and stored in ~~said~~the header information of ~~said~~the contents data.

82. (AMENDED) A recording program ~~supply~~ medium that supplies recorded with a computer program that ~~allows a computer system to execute~~ for processing of contents data supplied from a storage medium or a communication medium, said computer program comprising:

~~a list extracting step of extracting an illegal device list included in~~ said~~the~~ contents data;

~~a collation processing step of executing collation between entries included in~~ said~~the~~ illegal device list ~~extracted in said list extracting step and said data processing apparatus identifiers stored in a storage section in~~ at~~the~~ data processing apparatus; and

~~a step of stopping execution of processing of~~ either at least one of reproduction of said contents data or processing of storage in a recording device when ~~the~~a result of said~~the~~ collation processing in ~~said collation processing~~

step shows that said illegal device list includes information that matches said data processing apparatus identifiers.

83. (AMENDED) A data processing apparatus that processes contents data supplied via a recording medium or a communication medium, comprising:

an encryption processing section that executes encryption processing on said contents data;

a control section that executes control over said encryption processing section;

a system common key used for said encryption processing in said encryption processing section, which is common to ~~ethera~~ a plurality of data processing apparatuses using said contents data, said plurality of data processing apparatuses including said data processing apparatus; and

at least one of an apparatus-specific key, ~~which is specific to the data processing apparatus used for encryption processing in said encryption processing section or~~ and an apparatus-specific identifier, said apparatus-specific key being specific to said data processing apparatus and said apparatus-specific identifier being used to generate said apparatus-specific key, characterized in that ~~wherein~~

said encryption processing section is configured to perform said encryption processing by applying either one of said system common key and ~~or~~ said apparatus-specific key according to the a utilization mode of said contents data.

84. (AMENDED) The data processing apparatus according to Claim 83, ~~characterized in that~~ wherein said encryption processing section executes said encryption processing by applying either said one of said system common key and ~~or~~ said apparatus-specific key according to utilization restriction information included in said contents data.

85. (AMENDED) The data processing apparatus according to Claim 83, ~~further comprising including~~ a recording device for recording said contents data, characterized in that wherein:

~~said encryption processing section, when said utilization mode restricts usage of imposed with a utilization restriction that said contents data should be used only for the to said own~~ data processing apparatus, ~~generates data to be stored in said recording device is generated by executing said encryption processing using said apparatus-specific key on for said contents data; and~~

~~where said utilization mode permits usage of in the case where said contents data is also made available to any at least one of said plurality of data processing apparatuses other than said the own~~ data processing apparatus, said data to be stored in said recording device is generated by executing said encryption processing using said system common key on said contents data.

86. (AMENDED) The data processing apparatus according to Claim 83, ~~comprising further including~~ a signature key Kdev ~~specific to the data processing apparatus and a system signature key Ksys, said signature key Kdev being specific to said data processing apparatus and said system signature key Ksys being common to said a~~ plurality of data processing apparatuses, ~~characterized in that~~ wherein:

~~said encryption processing section, when said contents data is stored in said a recording device, said contents data being restricted to use by imposed with a utilization restriction that said contents data should be used only for the own said data processing apparatus, said encryption processing section generates an apparatus-specific check value through said encryption processing by applying said apparatus-specific signature key Kdev to said contents data and;~~

when said contents data is stored in said recording device, ~~with said contents data also being made available for use by at least one of said plurality of to an data processing apparatuses other than the own said data processing apparatus,~~ said encryption processing section generates an overall check value through said encryption processing by applying said system signature key Ksys to said contents data; and

~~said control section performs control of storing said contents data in said recording device together with either one of said apparatus-specific check value generated by said encryption processing section or and said overall check value together with said contents data in said recording device.~~

87. (AMENDED) The data processing apparatus according to Claim 83, ~~comprising further including a signature key Kdev specific to the data processing apparatus and a system signature key Ksys, said signature key Kdev being specific to said data processing apparatus and said system signature key Ksys being common to a said plurality of data processing apparatuses, characterized in that~~ wherein:

~~said encryption processing section, when said utilization mode restricts usage of contents data imposed with a utilization restriction that said contents data should be used only for the own to said data processing apparatus, and said contents data is reproduced, said encryption processing section generates an apparatus-specific check value by applying said apparatus-specific signature key Kdev to said contents data and executes performing collation processing on said apparatus-specific check value generated and,~~

when said utilization mode permits usage of said contents data also made available to an by at least one of said plurality of data processing apparatuses other than said the own data processing apparatus, and said contents data is

reproduced, said encryption processing section generates an overall check value ~~through encryption processing by~~ applying said system signature key Ksys to said contents data and performing collation processing on said overall check value generated; and

said control section generates reproducible decrypted data by continuing processing of said contents data by the encryption processing section only when said collation processing on ~~with~~ said apparatus-specific check value is established or when said collation processing on ~~with~~ said overall check value is established.

88. (AMENDED) The data processing apparatus according to Claim 83, ~~comprising further including a recording data processing apparatus signature key master key MKdev and a data processing apparatus identifier IDdev, characterized in that~~ wherein

said encryption processing section generates a signature key Kdev ~~as the data processing apparatus specific key through~~ said encryption processing based on said data processing apparatus signature key master key MKdev and said data processing apparatus identifier IDdev.

89. (AMENDED) The data processing apparatus according to Claim 88, ~~characterized in that~~ wherein said encryption processing section generates said signature key Kdev through DES encryption processing by applying said data processing apparatus signature key master key MKdev to said data processing apparatus identifier IDdev.

90. (AMENDED) The data processing apparatus according to Claim 83, ~~characterized in that~~ wherein said encryption processing section generates an intermediate integrity check value by executing said encryption processing on said contents

data, ~~and executes~~ said encryption processing including
applying one of said data-processing-apparatus-specific key
~~or~~ and said system common key to said intermediate integrity
check value.

91. (AMENDED) The data processing apparatus according to
Claim 90, ~~characterized in that~~wherein said encryption
processing section generates a partial integrity check value
through said encryption processing on a partial data set
containing at least one partial data item obtained by dividing
said contents data into a plurality of parts and generates an
said intermediate integrity check value through said
encryption processing on a partial integrity check value set
data string containing said partial integrity check value
generated.

92. (AMENDED) A data processing method for a data processing
apparatus that processes contents data supplied via a
recording medium or a communication medium, said method
~~characterized by comprising:~~

selecting, according to a utilization mode of said
contents data, an encryption processing key from among either
~~one of an encryption processing system common key common to~~
~~other data processing apparatuses using said contents data or~~
and an apparatus-specific key, said encryption processing
system common key being common to a plurality of data
processing apparatuses using said contents data, said
plurality of data processing apparatuses including said data
processing apparatus, and said apparatus-specific key which
being is specific to the said data processing apparatus
~~according to the utilization mode of said contents data; and~~

executing encryption processing by applying the said
~~selected encryption processing key~~ to said contents data.

93. (AMENDED) The data processing method according to Claim 92, ~~characterized in that~~wherein said step of encryption processing key-selecting said encryption processing key step ~~is a step of~~includes selecting said encryption processing key according to utilization restriction information contained in said contents data.

94. (AMENDED) The data processing method according to Claim 92, ~~characterized in that~~further including: the processing of storing contents data in the recording device,

~~when imposed with a utilization restriction that said contents data should be used only for the own data processing apparatus,~~ generates generating data to be stored in said a recording device by executing said encryption processing using applying said apparatus-specific key ~~on~~ on said contents data when said utilization mode restricts usage of said contents data to said data processing apparatus; and

~~in the case where said contents data is also made available to an apparatus other than the own data processing apparatus,~~ generating said data to be stored in said recording device is generated by executing said encryption processing using said encryption processing system common key on said contents data when said utilization mode permits usage of said contents data by at least one of said plurality of data processing apparatuses other than said data processing apparatus.

95. (AMENDED) The data processing method according to Claim 92, ~~characterized in that~~further including:

~~when said contents data is stored in said recording device imposed with a utilization restriction that said contents data should be used only for the own data processing apparatus,~~ the processing of recording contents data in the recording device generates generating an apparatus-specific

check value through said encryption processing by applying
~~said an~~ apparatus-specific signature key Kdev to said contents
data when said contents data is restricted to use by said data
processing apparatus and is stored in said recording device
and i

~~when said contents data is stored in said recording~~
~~device with said contents data also made available to an~~
~~apparatus other than the own data processing apparatus,~~
~~generates~~ generating an overall check value through said
encryption processing by applying said a system signature key
Ksys to said contents data when said contents data is
available for use by at least one of said plurality of data
processing apparatuses other than said data processing
apparatus and is stored in said recording device; and

~~either one of said apparatus specific check value~~
~~generated or said overall check value is stored~~ storing
~~together with said contents data in said recording device~~
together with one of said apparatus-specific check value and
said overall check value.

96. (AMENDED) The data processing method according to Claim
92, ~~characterized in that~~ further including:

~~when reproducing said contents data, wherein said~~
utilization mode restricts usage of ~~imposed with a utilization~~
~~restriction that said contents data should be used only for~~
~~the own by said data processing apparatus is reproduced, the~~
~~contents data reproducing processing:~~

~~generates~~ generating an apparatus-specific check
value through said encryption processing by applying said an
apparatus-specific signature key Kdev to said contents data,
and

~~executes~~ performing collation processing on said
apparatus-specific check value ~~generated and;~~

~~when reproducing said contents data, wherein said utilization mode permits usage of said imposed with a utilization restriction that the contents data is also made available to an by at least one of said plurality of data processing apparatuses other than the own said data processing apparatus is reproduced,;~~

~~generates generating an overall check value through said encryption processing by applying said a system signature key Ksys to said contents data, and~~

~~performs performing collation processing on said overall check value generated; and~~

~~contents data is reproduced reproducing said contents data only when said collation processing onwith said apparatus-specific check value is established or when said collation processing onwith said overall check value is established.~~

97. (AMENDED) The data processing method according to Claim 92, further comprising ~~a step of generating a signature key Kdev as the data processing apparatus specific key through said encryption processing based on a data processing apparatus signature key master key MKdev and a data processing apparatus identifier IDdev.~~

98. (AMENDED) The data processing method according to Claim 97, ~~characterized in that~~wherein said step of generating said signature key Kdev generating step is a step of generating said signature key Kdev throughincludes DES encryption processing by applying said data processing apparatus signature key master key MKdev to said data processing apparatus identifier IDdev.

99. (AMENDED) The data processing method according to Claim 92, further comprising ~~a step of generating an~~

intermediate integrity check value by executing said encryption processing on said contents data, ~~characterized by executing said encryption processing including applying one of said data processing apparatus-specific key or and said system common key to said intermediate integrity check value.~~

100. (AMENDED) The data processing method according to Claim 99, ~~characterized by further including:~~

generating a partial integrity check value through said encryption processing on a partial data set containing at least one partial data item obtained by dividing said contents data into a plurality of parts; and

generating ~~an~~ said intermediate integrity check value through said encryption processing on a partial integrity check value set data string containing said partial integrity check value-generated.

101. (AMENDED) A ~~recording program supply medium that supplies recorded with a computer program for a data processing apparatus, said computer program allowing a computer system to execute data processing that processes contents data supplied via a recording medium or a communication medium, said computer program comprising the steps of:~~

selecting, according to a utilization mode of said contents data, a key from among either an encryption processing key, an encryption processing system common key common to other data processing apparatuses using said contents data or and an apparatus-specific key, said encryption processing system common key being common to a plurality of data processing apparatuses using said contents data, said plurality of data processing apparatuses including said data processing apparatus, and said apparatus-specific key being ~~which is specific to the~~ said data processing

~~apparatus according to the utilization mode of said contents data; and~~

executing encryption processing by applying said~~the~~
~~selected encryption processing key to said contents data.~~

102. (AMENDED) A data processing apparatus that processes contents data supplied via a recording medium or a communication medium, comprising:

an encryption processing section that executes encryption processing on said contents data, said encryption processing section being configured to generate a contents check value in units of contents block data included in said contents data and to execute collation processing on said contents check value and thereby execute verification processing as to the validity of each of said units of contents block data; and

a control section that executes control over said encryption processing section, ~~characterized in that.~~

~~said encryption processing section is configured to generate a contents check value in units of contents block data to be verified included in the data, execute collation on the contents check value generated and thereby execute verification processing on the validity of each contents block data in said data.~~

103. (AMENDED) The data processing apparatus according to Claim 102, ~~comprising further including~~ a contents check value generation key, ~~characterized in that wherein~~ said encryption processing section generates a contents intermediate value based on said contents block data to be verified and said encryption processing system generates a said contents check value by executing encryption processing applying said

contents check value generation key to said contents intermediate value.

104. (AMENDED) The data processing apparatus according to Claim 103, ~~characterized in that~~wherein:

~~-when the~~said contents block data ~~to be verified~~ is encrypted, said encryption processing section generates a said contents intermediate value by executing predetermined operation processing on an entire decrypted statement in units of a predetermined number of bytes, said entire decrypted statement being obtained through~~by~~ decryption processing of said contents block data ~~in units of a predetermined number of bytes,~~; and

when ~~said~~the contents block data ~~to be verified~~ is not encrypted, said encryption processing section generates a said contents intermediate value by executing said predetermined operation processing on ~~the~~said entire contents block data in said units of a said predetermined number of bytes.

105. (AMENDED) The data processing apparatus according to Claim 104, ~~characterized in that~~wherein said predetermined operation ~~processing~~ applied in said intermediate integrity check ~~value generation processing by said encryption processing section~~ is an exclusive-OR operation.

106. (AMENDED) The data processing apparatus according to Claim 104, ~~characterized in that~~wherein:

~~-said encryption processing section has an encryption processing configuration in a~~ CBC mode; and

~~said decryption processing applied to the content intermediate value generation processing when the contents block data to be verified is decryption processing in~~ said CBC mode.

107. (AMENDED) The data processing apparatus according to Claim 106, ~~characterized in that~~wherein ~~the~~said encryption processing configuration in said CBC mode ~~of said encryption processing section~~ is a configuration in which common key encryption processing is applied a plurality of times only to part of a message string ~~to be processed~~.

108. (AMENDED) The data processing apparatus according to Claim 102, ~~characterized in that~~wherein, when ~~the~~said contents block data contains a plurality of parts and ~~some~~ a portion of said plurality of parts included in said contents block data ~~are~~is to be verified, said encryption processing section generates ~~a~~ said contents check value based on ~~said parts~~ portion to be verified, and ~~executes said collation processing on the~~said contents check value generated ~~and thereby executes verification processing on the validity in units of content block data in said data~~.

109. (AMENDED) The data processing apparatus according to Claim 108, ~~characterized in that~~wherein, ~~when said contents block data contains a plurality of parts and it is one part that needs to be verified,~~ when said portion is encrypted:

said encryption processing section generates ~~a~~ said contents check value by ~~executing encryption processing applying the~~ a contents check value generation key to a value obtained by carrying out an exclusive-OR in units of a predetermined number of bytes on ~~the~~ an entire decrypted statement, said entire decrypted statement being obtained by decryption processing of ~~parts to be verified~~ said portion in the case where said parts to be verified is encrypted,; and

when said portion is not encrypted:

said encryption processing section generates ~~a~~ said contents check value by ~~executing encryption processing~~

applying said contents check value generation key to a said value ~~obtained by carrying out an exclusive OR in units of a predetermined number of bytes on said entire part to be verified in the case where said parts to be verified is not encrypted.~~

110. (AMENDED) The data processing apparatus according to Claim 108, ~~characterized in that~~wherein, when said contents block data contains a plurality of parts and it is a portion of said plurality of parts that needs to be verified, said encryption processing section applies a contents check value generation key to said portion of said plurality of parts to obtain a parts check value~~uses, as a contents check value, the result obtained by executing encryption processing applying~~ies said contents check value generation key to link data of a said parts check value to obtain a result, and uses said result by executing encryption processing applying as said contents check value generation key to each part.

111. (AMENDED) The data processing apparatus according to Claim 102, ~~characterized in that~~wherein said encryption processing section further comprises a recording device for storing said contents data containing said units of contents block data whose validity has been verified.

112. (AMENDED) The data processing apparatus according to Claim 111, ~~characterized in that~~wherein, when said collation processing is not executed~~established in the collation processing on a said contents check value in said encryption processing section~~, said control section stops said storage in said recording device.

113. (AMENDED) The data processing apparatus according to Claim 102, ~~characterized in that~~wherein said encryption

processing section further comprises a reproduction processing section for reproducing data whose validity has been verified.

114. (AMENDED) The data processing apparatus according to Claim 113, ~~characterized in that~~wherein, when said collation processing is not executed~~established in the collation processing~~ on a said contents check value in ~~said encryption processing~~ section, said control section stops said reproduction processing in said reproduction processing section.

115. (AMENDED) A data processing method that processes contents data supplied via a recording medium or a communication medium, ~~characterized by~~comprising:

- generating a contents check value in units of contents block data ~~to be verified~~ included in said the contents data; and

- executing collation processing on said the contents check value ~~generated~~ and thereby executing verification processing ~~on the~~as to the validity ~~of~~in said units of contents block data ~~in said data~~.

116. (AMENDED) The data processing method according to Claim 115, ~~characterized by~~further including:

- generating a contents intermediate value based on said contents block data ~~to be verified~~; and

- generating a said contents check value by executing encryption processing by applying said contents check value generation key to said contents intermediate value ~~generated~~.

117. (AMENDED) The data processing method according to Claim 115, ~~characterized by~~further including:

- ~~generating,~~ when the said contents block data ~~to be verified~~ is encrypted, generating a contents intermediate

value by executing predetermined operation processing on an entire decrypted statement in units of a predetermined number of bytes, said entire decrypted statement being obtained ~~by~~through decryption processing of said contents block data ~~in units of a predetermined number of bytes~~,; and

~~generating, when the~~said contents block data ~~to be verified~~ is not encrypted, generating asaid contents intermediate value by executing said predetermined operation processing on saidthe entire contents block data in said units of a said predetermined number of bytes.

118. (AMENDED) The data processing method according to Claim 117, ~~characterized in that~~wherein said predetermined operation processing applied ~~in said intermediate integrity check value generation processing~~ is an exclusive-OR operation.

119. (AMENDED) The data processing method according to Claim 117, ~~characterized in that in said contents intermediate value generation processing~~,wherein said decryption processing applied ~~to the content intermediate value generation processing when the contents block data to be verified is encrypted~~ is decryption processing in a CBC mode.

120. (AMENDED) The data processing method according to Claim 119, ~~characterized in that~~wherein, in said step of decryption processing ~~configuration~~ in said CBC mode, common key encryption processing is applied a plurality of times only to part of a message string ~~to be processed~~.

121. (AMENDED) The data processing method according to Claim 115, ~~characterized by further including~~, generating, when saidthe contents block data contains a plurality of parts and ~~some~~a portion of said plurality of parts ~~included in said~~

~~contents block data are~~is to be verified, generating a said
contents check value based on said portion~~the~~ to be verified
prior to executing said parts to be verified,~~executing~~
collation processing on the~~said~~contents check value generated
and thereby executing verification processing on the validity
in units of content block data in said data.

122. (AMENDED) The data processing method according to
Claim 121, ~~characterized by~~further including:

when said portion is encrypted:

performing decryption processing of said portion to
obtain an entire decrypted statement,

carrying out an exclusive-OR operation in units of a
predetermined number of bytes on said entire decrypted
statement, and

generating,~~when the contents block data contains a~~
~~plurality of parts and it is one part that needs to be~~
~~verified,~~a said contents check value by executing encryption
processing applying the~~a~~contents check value generation key
to a value obtained by carrying out a~~said~~exclusive-OR
operation; and

when said portion is not encrypted:

in units of a predetermined number of bytes on the
entire decrypted statement obtained by decryption processing
of parts to be verified in the case where said part to be
verified is encrypted, and generating a~~said~~contents check
value by executing encryption processing applying said
contents check value generation key to a~~said~~value obtained
by carrying out an exclusive OR in units of a predetermined
number of bytes on said entire part to be verified in the case
where said part to be verified is not encrypted.

123. (AMENDED) The data processing method according to
Claim 121, ~~characterized by using,~~when said contents block

~~data contains a plurality of parts and it is a plurality of parts that needs to be verified, as a contents check value, the result obtained by executing encryption processing further applying said contents check value generation key to link data of a parts check value obtained by executing encryption processing applying the contents check value generation key to each part~~further including:

applying a contents check value generation key to each of said plurality of parts to obtain a parts check value;

further applying said contents check value generation key to link data of said parts check value to obtain a result; and

using said result as said contents check value.

124. (AMENDED) The data processing method according to Claim 115, ~~further comprising a step of~~including storing said contents data containing said units of contents block data whose validity has been verified.

125. (AMENDED) The data processing method according to Claim 124, ~~characterized in that~~further including stopping said storing of said contents data when said collation processing is not executed~~established in the collation processing on a said contents check value, said control section stops storage in said recording device.~~

126. (AMENDED) The data processing method according to Claim 115, ~~further comprising a step of~~including reproducing data whose validity has been verified.

127. (AMENDED) The data processing method according to Claim 126, ~~characterized by~~further including stopping said reproduction processing when said collation processing is not executed~~established on a said contents check value.~~

128. (AMENDED) A contents data verification value assignment method for contents data verification processing, ~~characterized by comprising:~~

~~-generating a contents check value in units of contents block data to be verified, said contents block data being included in said the contents data,;~~ and

~~assigning said the contents check value generated to said contents data containing the contents block data to be verified.~~

129. (AMENDED) The contents data verification value assignment method according to Claim 128, ~~characterized in that~~wherein said contents check value is generated through encryption processing ~~by applying the a~~ contents check value generation key using said the contents block data ~~to be checked~~ as a message.

130. (AMENDED) The contents data verification value assignment method according to Claim 128, ~~characterized in that~~wherein:

~~said contents check value is generated by generating a contents intermediate value based on said the contents block data to be verified and executing encryption processing applying a~~said contents check value generation key to said contents intermediate value.

131. (AMENDED) The contents data verification value assignment method according to Claim 128, ~~characterized in that~~wherein said contents check value is generated by executing encryption processing on said contents block data in a CBC mode on the contents block data to be verified.

132. (AMENDED) The contents data verification value assignment method according to Claim 131, ~~characterized in that~~wherein said ~~encryption processing configuration in~~ CBC mode is a configuration in which common key encryption processing is applied a plurality of times only to part of a message string ~~to be processed~~.

133. (AMENDED) The contents data verification value assignment method according to Claim 128, ~~characterized by generating, when~~wherein ~~said~~the contents block data contains a plurality of parts and ~~some parts included in said contents block data~~a portion of said plurality of parts ~~are~~ is to be verified, said method further comprising:

generating a said contents check value based on
~~said~~the parts ~~to be verified~~portion; and

assigning ~~said~~the contents check value generated to
~~said contents data containing the content block data to be~~
verified.

134. (AMENDED) The contents data verification value assignment method according to Claim 133, ~~characterized by~~further including:

when said portion is encrypted:

performing decryption processing of said portion to
obtain an entire decrypted statement,

carrying out an exclusive-OR operation in units of a
predetermined number of bytes on said entire decrypted
statement to obtain a value, and

generating said contents check value by applying a
contents check value generation key to said value; and

when said portion is not encrypted:

generating said contents check value by applying
said contents check value generation key to said value.

~~generating, when said contents block data contains a plurality of parts and it is one part that needs to be verified, a contents check value by executing encryption processing applying the contents check value generation key to a value obtained by carrying out an exclusive OR in units of a predetermined number of bytes on the entire decrypted statement obtained by decryption processing of parts to be verified in the case where said parts to be verified is encrypted, generating a contents check value by executing encryption processing applying said contents check value generation key to a value obtained by carrying out an exclusive OR in units of a predetermined number of bytes on said entire part to be verified in the case where said parts to be verified is not encrypted and assigning the contents check value generated to the contents data containing the contents block data to be verified.~~

135. (AMENDED) The contents data verification value assignment method according to Claim 133, ~~characterized by using, when said contents block data contains a plurality of parts and it is a plurality of parts that needs to be verified, as a contents check value, the result obtained by executing encryption processing further applying said contents check value generation key to link data of a parts check value obtained by executing encryption processing applying the contents check value generation key to each part and assigning the contents check value generated to contents data containing the contents block data to be verified.~~further including:

applying a contents check value generation key to each of said plurality of parts to obtain a parts check value;

further applying said contents check value generation key to link data of said parts check value to obtain a result; and

using said result as said contents check value.

136. (AMENDED) A ~~recording~~program ~~supply~~ medium that ~~supplies~~recorded with a computer program to ~~execute~~ for executing data processing on contents data supplied via a recording medium or a communication medium, said computer program comprising:

~~a step of generating a contents check value in units of contents block data to be verified included in the~~said contents data; and

~~a step of executing collation processing on the~~said contents check value generated and thereby executing verification processing ~~on the~~as to the validity in ~~of said units of contents block data in said data.~~

137. (AMENDED) A data processing apparatus ~~for executing processing for~~ generating storing data with respect to a ~~recording device~~ effor recording content data, said content data including~~which has~~ a plurality of content blocks ~~in which at least a part of the blocks are encrypted and a header section, at least a part of said plurality of content blocks being encrypted and said header section being operable to storing information on the~~said contents blocks, said content data being structured by encryption key data Kdis[Kcon] stored in said header section, said encryption key data Kdis[Kcon] being formed by applying an encryption key Kdis to an encryption key Kcon, e~~characterized in that~~said data processing apparatus comprising:

~~in the case in which content data to be an object of storage in said recording device is structured by data stored in said header section, which is an encryption key data Kdis[Keon] that is an encryption key Keon of said content block applied encryption processing by an encryption key Kdis,~~

~~said data processing apparatus has a structure~~

~~for executing processing for taking out~~means for removing said encryption key data Kdis[Kcon] from said header section; and

means for executing decryption processing on said encryption key data Kdis[Kcon] to generate decryption data Kcon,;

means for generating a new encryption key data Kstr[Kcon]~~that is by applied~~applying encryption processing by an encryption key Kstr to said decryption data Kcon; and

means for storing said~~the new encryption key data Kstr[Kcon] in said~~the header section of said content data,; and

means for applying a different encryption key Kstr to said~~the generated decryption data Kcon to execute decryption encryption processing.~~

138. (AMENDED) A data processing apparatus ~~for executing processing for~~ generating storing data with respect to a ~~recording device for recording~~ef content data, ~~which has~~said content data including a plurality of content blocks ~~in which at least a part of the blocks are encrypted~~ and a header section, at least a part of said plurality of content blocks being encrypted and said header section being operable to storing information on said~~the contents~~ blocks, said plurality of content blocks being composed of contents encrypted by an encryption key Kblc and encryption key data Kcon[Kblc], said encryption key data Kcon[Kblc] being formed by applying an encryption key Kcon to said encryption key Kblc, and said plurality of content blocks having a structure in which encryption key data Kdis[Kcon] is stored in said header section, said encryption key data Kdis[Kcon] being formed by applying an encryption key Kdis to said encryption key Kcon, ~~characterized in that~~said data processing apparatus comprising:

~~in the case in which said content block included in content data to be an object of storage with respect to said recording device is composed of contents encrypted by an encryption key Kble and encryption key data Keon[Kble] that is encrypted by the encryption key Keon, and has a structure in which encryption key data Kdis[Kcon] that is the encryption key Keon applied encryption processing by an encryption key Kdis is stored in said header section,~~

~~said data processing apparatus has a structure for executing processing for taking out~~means for removing said encryption key data Kdis[Kcon] from said header section;

means for executing decryption processing on said encryption key data Kdis[Kcon] to generate decryption data Kcon,

means for generating a new encryption key data Kstr[Kcon] that is applied by applying encryption processing by an encryption key Kstr to said decryption data Kcon; and

means for storing said new~~the~~ encryption key data Kstr[Kcon] in said~~the~~ header section of said content data;

and

means for applying a different encryption key Kstr to said~~the~~ generated decryption data Kcon to execute decryption encryption processing.

139. (AMENDED) A data processing apparatus ~~for executing processing for~~ generating storing data with respect to a ~~recording device~~ for recording content data, ~~which has said content data including a plurality of content blocks in which at least a part of the blocks are encrypted and a header section, at least a part of said plurality of content blocks being encrypted and said header section being operable to storing information on the said plurality of contents blocks, said plurality of content blocks being composed of contents~~

encrypted by an encryption key Kblc and encryption key data Kdis[Kblc], said encryption key data Kdis[Kblc] being formed by applying an encryption key Kdis to said encryption key Kblc, said data processing apparatus comprising~~characterized in that:~~

~~— in the case in which said content block included in content data to be an object of storage with respect to said recording device is composed of contents encrypted by an encryption key Kble and encryption key data Kdis[Kble] that is encrypted by the encryption key Kdis,~~

~~said data processing apparatus has a structure~~

~~means for removing~~ for executing processing for taking out said encryption key data Kdis[Kblc] from said a content block section;

means for executing decryption processing of the~~said encryption key data Kdis[Kblc] Kble to generate decryption data Kblc,—;~~

means for generating an encryption key data Kstr[Kblc] that is applied encryption processing by applying an encryption key Kstr and to said decryption data Kblc;

means for storing the~~said encryption key data Kstr[Kblc] in a said contents block section,—;~~ and

means for applying a different encryption key Kstr to said the generated decryption data Kblc to execute decryption encryption processing.

140. (AMENDED) A content data generating method for generating content data, comprising:

coupling a plurality of content blocks~~composed of data including at least any one of voice information, image information and program data;~~

applying encryption processing to at least a part of said content blocks included in said plurality of content blocks by using an encryption key Kcon;

generating encryption key data Kdis[Kcon] by applying an encryption key Kdis to said encryption key Kcon; ~~that is said encryption key Keon applied encryption processing by an encryption key Kdis and~~

storing ~~thesaid~~ encryption key Kdis in a header section of said content data; and

generating said content data including said plurality of content blocks and ~~thesaid~~ header section.

141. (AMENDED) The content data generating method according to Claim 140, ~~characterized in that said content data generating method further comprises including~~processing of:

generating block information that stores ~~information including~~at least one of :

identification information on said content data, ;

usage policy information including a data length of ~~thesaid~~ content data and a data type of ~~thesaid~~ content data, and,

~~information including~~a data length of at least one of said content blocks, and

a presence or absence of encryption processing, ;

and

storing ~~saidthe~~ block information in said header section.

142. (AMENDED) The content data generating method according to Claim 140, ~~characterized in that said content data generating method further comprises processing of~~including:

generating a part check value based on a part portion of information composing said header section; and

storing ~~saidthe~~ part check value in said header section; and

generating a total check value based on said part check value; and

storing said~~the~~ total check value in said header section.

143. (AMENDED) The content data generating method according to Claim 142, ~~characterized in that~~wherein said steps of ~~generation-generating processing of said part check value and generation-generating processing of said total check value are executed by applying a DES encryption processing algorithm with using data to be an object of checked as a message and using a check value generation key as an encryption key.~~

144. (AMENDED) The content data generating method according to Claim 141, ~~characterized in that said content data generating method further comprises~~including:

applying said encryption processing to said block information by applying said encryption key Kdis to an~~the~~ encryption key Kbit to form encryption key data Kdis[Kbit]; and

storing said~~the~~ encryption key data Kdis[Kbit] ~~that is the encryption key Kbit generated by the encryption key Kdis in said header section.~~

145. (AMENDED) The content data generating method according to Claim 140, ~~characterized in that~~wherein each block of a said plurality of content blocks in said content block is generated as a common fixed data length.

146. (AMENDED) The content data generating method according to Claim 140, ~~characterized in that~~wherein each block of a said plurality of content blocks in said content block is generated ~~as a configuration in which~~with an encryption data section and a non-encryption data section ~~are arranged regularly.~~

147. (AMENDED) A content data generating method for generating content data, comprising:

coupling a plurality of content blocks each including at least ~~any one~~ of voice information, image information and program data;

composing at least a part of ~~thesaid~~ plurality of content blocks by ~~an encryption data section that is data including at least any one of voice information, image information and program data~~ applying an encryption key Kcon to ~~by an encryption key Kblc, and to obtain a set of encryption key data Kcon[Kblc] that is the encryption key Kble of the encryption data section applied encryption processing by an encryption key Keon;~~

generating encryption key data Kdis[Kcon] by applying an encryption key Kdis to ~~that is thesaid encryption key Kcon applied encryption processing by an encryption key Kdis;~~ and

storing said encryption key data Kdis[Kcon] in a header section of said content data; and

generating said content data including a said plurality of content blocks and a said header section.

148. (AMENDED) A content data generating method for generating content data, comprising:

coupling a plurality of content blocks each including at least ~~any one~~ of voice information, image information and program data;

composing at least a part of ~~thesaid~~ plurality of content blocks by ~~an encryption data section~~ applying an encryption key Kdis to an encryption key Kblc to obtain encryption key data Kdis[Kblc] ~~that is data including at least any one of voice information, image information and program data by an encryption key Kble, and a set of encryption key data Kdis[Kble] that is the encryption key Kble of the~~

~~encryption data section applied encryption processing by an encryption key Kdis; and~~

generating said content data including a ~~said~~ plurality of content blocks and a header section of said content data.

149. (AMENDED) A data processing method for ~~executing processing for storing content data~~ in a recording device ~~of content data~~, said content data having a plurality of content blocks ~~in which at least a part of blocks are encrypted~~, and a header section, at least a part of said plurality of content blocks being encrypted and said header section being operable to store in which information on the said plurality of content blocks is stored, said content data being structured by encryption key data Kdis[Kcon] stored in said header section, said encryption key data Kdis[Kcon] being formed by applying an encryption key Kdis to an encryption key Kcon, said method comprising:

~~in the case in which content data to be an object of storage in said recording device is structured by data stored in said header section, which is an encryption key data Kdis[Keon] that is an encryption key Keon of said content block applied encryption processing by an encryption key Kdis,~~

~~taking out~~removing said encryption key data Kdis[Kcon] from said header section; ~~and~~

~~executing decryption processing on said encryption key data Kdis[Kcon] to generate decryption data Kcon;~~

generating a ~~new encryption key data Kstr[Kcon] that is applied encryption processing by an encryption key Kstr by applying a different an encryption key Kstr to said the generated decryption data Kcon to execute encryption processing; and~~

storing said ~~generated new~~ encryption key data Kstr[Kcon] in a said header section ~~of said content data;~~ and

storing ~~the~~said header section in said recording device together with said plurality of content blocks.

150. (AMENDED) A data processing method for ~~executing processing for storing content data in a recording device of,~~ said content data having a plurality of content blocks in which at least a part of blocks are encrypted, and a header section, at least a part of said plurality of content blocks being encrypted and said header section being operable to store in which information on the said plurality of content blocks is stored, said plurality of content blocks being composed of contents encrypted by an encryption key Kblc and encryption key data Kcon[Kblc], said encryption key data Kcon[Kblc] being formed by applying an encryption key Kcon to said encryption key Kblc, and said plurality of content blocks having a structure in which encryption key data Kdis[Kcon] is stored in said header section, said encryption key data Kdis[Kcon] being formed by applying an encryption key Kdis to said encryption key Kcon, said method comprising:

~~in the case in which said content blocks included in content data to be an object of storage with respect to said recording device is composed of contents encrypted by an encryption key Kble and encryption key data Keon[Kble] that is encrypted by the encryption key Keon, and has a structure in which encryption key data Kdis[Keon] that is the encryption key Keon applied encryption processing by an encryption key Kdis is stored in said header section,~~

~~taking out~~removing said encryption key data Kdis[Kcon] from said header section; and

executing decryption processing on said encryption key data Kdis[Kcon] to generate decryption data Kcon;

generating a new encryption key data Kstr[Kcon] that is applied encryption processing by an encryption key Kstr by

applying a ~~different~~n encryption key Kstr to ~~said~~the generated decryption data Kcon ~~to execute encryption processing~~; and

storing said ~~generated~~new encryption key data Kstr[Kcon] in a ~~said~~ header section of ~~said~~ content data,; and

storing ~~thesaid~~ header section in said recording device together with said plurality of content blocks.

151. (AMENDED) A data processing method for ~~executing processing for storing content data~~ in a recording device, of ~~said~~ content data having a plurality of content blocks in ~~which at least a part of blocks are encrypted~~, and a header section, at least a part of said plurality of content blocks being encrypted, and said header section being operable to store in which information on ~~thesaid~~ plurality of content blocks is stored, said plurality of content blocks being composed of contents encrypted by an encryption key Kblc and encryption key data Kdis[Kblc], said encryption key data Kdis[Kblc] being formed by applying an encryption key Kdis to said encryption key Kblc, said method comprising:

~~in the case in which said content block included in content data to be an object of storage with respect to said recording device is composed of contents encrypted by an encryption key Kble and encryption key data Kdis[Kble] that is encrypted by the encryption key Kdis,~~

~~taking out~~removing said encryption key data Kdis[Kblc] from ~~said~~a content block section; and

executing decryption processing of ~~thesaid~~ the encryption key data Kdis[Kblc] ~~Kble~~ to generate decryption data Kblc;

generating an encryption key data Kstr[Kblc] ~~that is applied encryption processing by an encryption key Kstr by applying a~~ ~~different~~n encryption key Kstr to ~~said~~the decryption data Kblc ~~to execute encryption processing~~; and

storing said ~~generated~~ encryption key data Kstr[Kblc] in asaid content block section; and

storing ~~saidthe~~ content block section in said recording device together with said plurality of content blocks.

152. (AMENDED) A ~~program providing~~ recording medium for ~~providing~~ recorded with a computer program causing generation processing of for generating storing data with respect to a recording device ~~effor~~ for recording content data, said content data which has including a plurality of content blocks in which at least a part of the blocks are encrypted and a header section, at least a part of said plurality of content blocks being encrypted and said header section being operable to storing store information on thesaid contents blocks, said content data being structured by encryption key data Kdis[Kcon] stored in said header section, said encryption key data Kdis[Kcon] being formed by applying an encryption key Kdis to an encryption key Kcon, ~~to be executed on a computer system, characterized in that:~~

~~—said computer program comprises~~ comprising:

~~in the case in which content data to be an object of storage in said recording device is structured by data stored in said header section, which is an encryption key data Kdis[Keon] that is an encryption key Keon of said content block applied encryption processing by an encryption key Kdis,~~

~~a step of taking out~~ removing said encryption key data Kdis[Kcon] from said header section; and

executing decryption processing on said encryption key data Kdis[Kcon] to generate decryption data Kcon;

generating a new encryption key data Kstr[Kcon] that is applied encryption processing by an encryption key Kstr by applying a ~~different~~ an encryption key Kstr to saidthe

generated decryption data Kcon ~~to execute encryption processing~~; and

storing said new generated ~~encryption~~ key data Kstr[Kcon] in a said header section of ~~said content data~~.

153. (AMENDED) A data processing apparatus for ~~performing reproduction processing of reproducing content data, said content data including compressed contents and an expansion processing program of said compressed contents, and being provided by a storage medium or a communication medium, characterized by~~ said data processing apparatus comprising:

a content data analyzing section for executing content data analysis of said ~~content data including compressed contents and an~~ said expansion processing program of said compressed contents, and being operable to executing extraction processing of the said compressed contents and the said expansion processing program from said content data; and

an expansion processing section for executing expansion processing of ~~the said content data included in said content data using an said expansion processing program included in the content data obtained as a result of the analysis of said content data analyzing section.~~

154. (AMENDED) The data processing apparatus according to Claim 153, ~~characterized by further comprising~~ including:

a data storing section for storing ~~the said compressed contents that are extracted by said content data analyzing section~~; and

a program storing section for storing ~~the said expansion processing program extracted by said content data analyzing section, and characterized in that~~ wherein said expansion processing section has a configuration for executing said expansion processing with respect to ~~the said~~ compressed

~~contents stored in said data storing section by applying the~~said expansion processing program ~~stored in said program storing section to the~~said compressed contents.

155. (AMENDED) The data processing apparatus according to Claim 153, ~~characterized in that~~wherein said contents data analyzing section has a configuration for obtaining a configuration information of said content data based on header information included in said content data, and said content data analyzing section is operable to performing analysis of thesaid content data.

156. (AMENDED) The data processing apparatus according to Claim 155, ~~characterized in that~~wherein:

-reproduction priority information of ~~the~~said compressed contents is included in said header information; and,

if there are a plurality of compressed contents ~~that is objects of expansion processing in said expansion processing section,~~ said expansion processing section has a configuration for sequentially executing content expansion processing in accordance with ~~the priority based on the~~said reproduction priority information in the header information obtained in said content data analyzing section.

157. (AMENDED) The data processing apparatus according to Claim 153, ~~characterized by further comprising~~including:

displaying means for displaying information of ~~said~~the compressed contents ~~that are objects of expansion processing;~~ and

inputting means for inputting reproduction contents identification data selected from ~~the content~~ said information displayed on said displaying means, and ~~characterized in that~~wherein said expansion processing section has a

configuration for executing said expansion processing of thesaid compressed contents corresponding to said ~~the~~ identification data based on the reproduction contents ~~identification data inputted from said inputting means.~~

158. (AMENDED) A data processing apparatus for ~~performing reproduction processing of~~ reproducing content data, said content data including one of compressed contents and an expansion processing program, and said content data being provided by a storage medium or a communication medium, ~~characterized by~~ said data processing apparatus comprising:

a content data analyzing section for receiving said ~~content data including either compressed contents or expansion processing program, said content data analyzing section being operable to distinguishing whether the~~ said content data has the ~~includes said~~ compressed contents or the ~~said~~ expansion processing program from header information included in the ~~said~~ received content data; and, at the same time,

if ~~the~~ said ~~content data has~~ includes said the ~~compressed contents, said content data analyzing section being operable to analyze obtaining a type of a compressing processing program applied to the~~ said ~~compressed contents from the~~ said ~~header information of the content data; and~~

if ~~the~~ said ~~content data has~~ includes said the ~~expansion processing program, said content data analyzing section being operable to analyze obtaining a type of the~~ expansion processing program from the ~~said~~ header information of the content data; and

an expansion processing section for executing expansion processing of thesaid ~~compressed contents, characterized in that said expansion processing section has having a configuration for selecting an a specific expansion processing program applicable to the~~ said ~~type of the compression processing program of the compressed contents~~

~~analyzed by said content data analyzing section based on~~
~~thesaid~~ type of ~~the~~ expansion processing program ~~analyzed by~~
~~said content data analyzing section, and being operable to~~
~~executeing~~ said expansion processing by using said specific
~~the selected expansion processing program.~~

159. (AMENDED) The data processing apparatus according to
Claim 158, ~~characterized by further comprising~~including:

a data storing section for storing ~~thesaid~~
compressed contents ~~that are extracted~~analyzed by said content
data analyzing section; and

a program storing section for storing said
specific~~the~~ expansion processing program ~~extracted by said~~
~~content data analyzing section, and characterized in~~
~~that~~wherein said expansion processing section has a
configuration for executing said expansion processing ~~with~~
~~respect to the compressed contents stored in said data storing~~
~~section by applying thesaid specific~~ expansion processing
program stored in said program storing section to ~~thesaid~~
compressed contents.

160. (AMENDED) The data processing apparatus according to
Claim 158, ~~characterized in that~~further including:

~~-reproduction priority information of associated~~
~~with thesaid~~ compressed contents, said reproduction priority
information being ~~is~~ included in said header information; and

if there are a plurality of compressed contents ~~that~~
~~is~~ objects of expansion processing, ~~content~~ said expansion
processing in said expansion processing section has a
configuration for sequentially executing ~~content~~ said
expansion processing in accordance with ~~the priority based on~~
the said reproduction priority information ~~in the header~~
~~information obtained in said content data analyzing section.~~

161. (AMENDED) The data processing apparatus according to Claim 158, ~~characterized by further comprising~~ including:

~~retrieving means for retrieving an said specific expansion processing program, and characterized in that said retrieving means has a configuration for retrieving an expansion processing program applicable to a type of the compression processing program of the compressed contents analyzed by said content data analyzing section; and~~

~~with program storing means accessible by said data processing apparatus as an object of retrieval.~~

162. (AMENDED) The data processing apparatus according to Claim 158, ~~characterized by further comprising~~ including:

~~displaying means for displaying information of the said compressed contents that are objects of expansion processing; and~~

~~inputting means for inputting reproduction contents identification data selected from the content said information displayed on said displaying means, and characterized in that wherein said expansion processing section has a configuration for executing said expansion processing of the said compressed contents corresponding to said reproduction contents identification data inputted from said inputting means.~~

163. (AMENDED) A data processing method for ~~reproducing~~ performing reproduction processing of content data, said content data including compressed contents and an expansion processing program of said compressed contents, said content data being provided by a storage medium or a communication medium, characterized by said method comprising:

~~a content data analyzing step of executing content data analysis of said content data including compressed~~

~~contents and an expansion processing program of said compressed contents, contents; and~~

~~executing extracting on processing of the said compressed contents and the said expansion processing program from said content data; and~~

~~an expansion processing step of executing expansion processing of the said compressed content included in said content data using an said expansion processing program included in the content data obtained as a result of the analysis of said content data analyzing step.~~

164. (AMENDED) The data processing method according to Claim 163, ~~characterized by further comprising~~including:

~~a data storing step of storing the said extracted compressed contents that are extracted by said content data analyzing step; and~~

~~a program storing step of storing the said extracted expansion processing program extracted by said content data analyzing section, and characterized in that wherein said expansion processing section has a configuration for executing expansion processing is executed with respect to the said compressed contents stored in said data storing step by applying the said expansion processing program stored in said program storing step to the said compressed contents.~~

165. (AMENDED) The data processing method according to Claim 163, ~~characterized in that said contents data analyzing step~~further including:

~~-obtaining a configuration information of said content data based on header information included in said content data and prior to executing said content data analysis performs analysis of the content data.~~

166. (AMENDED) The data processing method according to Claim 165, ~~characterized in that~~wherein:

~~—said reproduction priority information of the compressed contents includes reproduction priority information is included in said header information; and,~~

~~if there are a plurality of compressed contents that is objects of expansion processing in said expansion processing section, said expansion processing step sequentially executes content expansion processing in accordance with the priority based on the said reproduction priority information in the header information obtained in said content data analyzing step.~~

167. (AMENDED) The data processing method according to Claim 163, ~~characterized by further comprising~~including:

~~displaying step of displaying information of the said compressed contents that are objects of expansion processing on displaying means; and~~

~~inputting step of inputting reproduction contents identification data selected from the content said display and information displayed on said displaying means, and characterized in that, wherein said expansion processing step executes expansion processing of the compressed contents is performed corresponding to said the identification data based on reproduction contents identification data inputted from said inputting step.~~

168. (AMENDED) A data processing method for performing ~~reproduction processing of~~ reproducing content data, said content data including one of compressed contents and an expansion processing program, said content data being provided by a storage medium or a communication medium, characterized by said method comprising:

~~a content data analyzing step of receiving said content data including either compressed contents or expansion processing program;~~

distinguishing whether thesaid content data has theincludes said compressed contents or thesaid expansion processing program from header information included in the said received content data; ~~and, at the same time.~~

if thesaid content data ~~has theincludes said~~ compressed contents, ~~obtaining analyzing a type of a~~ compressing processing program applied to thesaid compressed contents from thesaid header information ~~of the content data;~~ and

if thesaid content data includes saidhas the expansion processing program, ~~obtaining analyzing a type of the~~ expansion processing program from thesaid header information ~~of the content data;~~

~~a selecting step of selecting an a specific~~ expansion processing program applicable to thesaid type of the compression processing program of the compressed contents analyzed in said content data analyzing step based on thesaid type of the expansion processing program analyzed in said content data analyzing step; and

~~an expansion processing step of executing expansion processing by using said specific the~~ expansion processing program ~~selected in said selecting step.~~

169. (AMENDED) The data processing method according to Claim 168, ~~characterized by further comprising~~including:

~~a data storing step of storing thesaid~~ compressed contents ~~that are extracted by said content data analyzing section;~~ and

~~a program storing step of storing thesaid specific~~ expansion processing program ~~extracted by said content data analyzing section,~~ and ~~characterized in that~~wherein said

~~expansion processing step executes expansion processing with respect to the compressed contents stored in said data storing step~~ is executed by applying the said specific expansion processing program stored in said program storing step to the said compressed contents.

170. (AMENDED) The data processing method according to Claim 168, ~~characterized in that~~ wherein:

~~-reproduction priority information of the~~ associated with said compressed contents, said reproduction priority information being ~~is~~ included in said header information; and,

~~if there are a plurality of compressed contents that is objects of expansion processing, said content expansion processing step including sequentially executes executing content~~ said expansion processing in accordance with the priority based on the said reproduction priority information in the header information obtained in said content data analyzing step.

171. (AMENDED) The data processing method according to Claim 168, ~~characterized by comprising~~ further including:

~~a retrieving step of retrieving an said specific expansion processing program, and characterized in that said retrieving step retrieves an expansion processing program applicable to a type of the compression processing program of the compressed contents analyzed in said content data analyzing step with from~~ a program storing means accessible by said data processing apparatus as an object of retrieval.

172. (AMENDED) The data processing method according to Claim 168, ~~characterized by further comprising~~ including:

~~a displaying step of displaying~~ information of said compressed contents on displaying means information of the

~~compressed contents that are objects of expansion processing;~~
and

~~an inputting step of inputting reproduction contents~~
identification data selected from the content said displayed
information, ~~displayed on said displaying means, and~~
~~characterized in that~~wherein ~~said expansion processing step~~
~~executes said expansion processing of~~ is performed on said~~the~~
compressed contents corresponding to the ~~identification data~~
~~based on the~~ said reproduction contents identification data
~~inputted from said inputting means.~~

173. (AMENDED) A content data generating method for
performing ~~generation processing of~~generating content data,
said content data being provided by a storage medium or a
communication medium, ~~characterized by~~comprising:

combining compressed contents and an expansion
processing program; and

~~generating said content data in which~~including said
compressed contents and ~~an~~ said expansion processing program
~~of the compressed contents are combined.~~

174. (AMENDED) The content data generating method according
to Claim 173, ~~characterized in that~~further including:

adding a configuration information of the content
~~data is added as~~ header information of said content data.

175. (AMENDED) The content data generating method according
to Claim 173, ~~characterized in that~~wherein said header
information includes reproduction priority information of
contents included in said~~the~~ content data ~~as header~~
~~information of the content data.~~

176. (AMENDED) A content data generating method for
performing ~~generation processing of~~generating content data,

said content data being provided by a storage medium or a communication medium, characterized in that content data
~~is~~said method comprising:

~~-generated in which a type of content data for~~
identifying whether ~~the~~said content data has, as header
information, compressed contents or an expansion processing
program ~~is added as header information;~~

if ~~the~~said content data has said compressed
contents, applying a type of a compression processing program
~~applied to the~~ said compressed contents ~~is added as header~~
information; and

if ~~the~~said content data has an ~~an~~said expansion
processing program, adding a type of an ~~an~~ expansion processing
program ~~is added as header information.~~

177. (AMENDED) The content data generating method according
to Claim 176, ~~characterized in that~~further including:

~~-adding~~ reproduction priority information ~~of~~
~~contents included in the content data is added as header~~
information of said content data.

178. (AMENDED) A ~~program providing~~recording medium recorded
~~with for providing~~ a computer program that causes a computer
~~system to execute reproduction processing of~~ for reproducing
content data, said content data including compressed contents
and an expansion processing program for said compressed
contents, and said content data being provided by a storage
medium or a communication medium, ~~characterized by~~ said
computer program comprising:

~~a content data analyzing step of executing content~~
data analysis of said content data ~~including compressed~~
~~contents and an expansion processing program of said~~
~~compressed contents,~~ i and

~~executing extraction processing of the~~extracting
said compressed contents and ~~the~~said expansion processing
program from said content data; and

~~an expansion processing step of executing expansion~~
processing of ~~the~~said extracted content data ~~included in said~~
~~content data using an~~ said extracted expansion processing
program ~~included in the content data obtained as a result of~~
~~the analysis of said content data analyzing section.~~
